MERSEY RAILWAY CO.—The report of the directors for the half-year ended June 30 states that the train mileage run during the six months was 326,063 miles, compared with 330,307 in the corresponding six months of 1910; passengers carried 6,027,753, against 5,948,152, exclusive of season ticket holders. Receipts from all sources were £55,796. 10s. 7d., compared with £54,652. 18s. 2d. Working expenses (exclusive of charges for pumping, ventilation, and lifts) were £26,426. 2s. 5d. (47·36 per cent.) against £28,916. 4s. (52·91 per cent.). Charges for pumping, ventilation and hydraulic lifts amounted to £2,798. 14s. 3d. (5·01 per cent.), compared with £3,279. 11s. 9d. (6·0 per cent.) £5,005. 11s. 2d. standing at the debit of the net revenue account at the close of the half-year ending Dec. 31, 1910, has been transferred and charged to the capital account. After providing for rent charges, renewal fund, and interest on new first perpetual debenture stock there is a balance at the credit of net revenue account of £8,061. 4s. 9d., which has been carried forward to Dec. 31 account.

METROPOLITAN RAILWAY CO.—The directors' report for the half-year to June 30 states that the total receipts were £400,735. 18s. 3d. (increase £9,247. 8s. 8d.), and expenses £195,666. 17s. 3d. (increase £1,646. 18s. 3d.), leaving £205,069. 1s. profit. After providing for interest and other fixed charges and placing £5,000 to electrical renewal and depreciation fund, there is a balance of £166,728. 6s. 6d., which will meet dividend payments on the preference stocks, and leave £61,424. 19s. 3d. available for dividend upon the ordinary stock. The Directors propose to declare a dividend on this stock for the half-year at the rate of £2 per cent., and to carry forward £4,104. 6s. 10d. This compares with £1. 5s. per cent. for the corresponding period of 1910, and a carry forward of £6,044. The dividend on the surplus lands stock, for the half year, will be at the rate of £3 per cent. During the half-year more "non-stop" trains have been introduced during the busy hours of the morning and evening, and the result has been a considerable increase in the issue of season tickets. Parcels and goods traffic continues to show satisfactory expansion. The installation of automatic signalling between Willesden Green and Neasden has been completed. The replacement of the existing electrical plant at Neasden by machines of larger capacity and improved economy is proceeding satisfactorily. Arrangements for the electrification of the East London Railway are engaging the special attention of the lessee companies, and the work is expected to be put in hand shortly. Its completion will permit of this company's train service over that railway to New Cross being resumed.

At the meeting on Wednesday the chairman (Lord Aberconway) said said they were charging £5,000 to electrical, renewal and depreciation fund, as against £10,000 a year ago. There had been an increase both in electrical and steam mileage. There was no doubt the maintenance of a frequent service within the Greater London area was the best advertisement the line could have. It had to borne in mind that competition was becoming keener and the number of motor omnibuses on the streets was increasing every week. The company had succeeded in getting a reduction of £26,852 on their rateable values assessment which meant a saving of about £10,000. This justified the view that railway property was unfairly treated by local authorities. The work under contract with the Westinghouse Co. for the replacement of the Metropolitan Co.'s generating plant at Neasden was proceeding satisfactorily. The work under the first of the Baker-street contracts was moving on rapidly, and within the last few days they had let the second principal

Digitized by Google

contract—for the alteration of the station buildings and platforms with a view to getting the second through road between the northern extension and the City. The construction of the arcade at Liverpool-street Station, connecting up New Broad-street and Liverpool-street, was rapidly approaching completion, and the new station and bridge at King's Cross were also being pushed forward as rapidly as circumstances permitted. It was only three years ago that the balance available for dividend on the ordinary stock was not more than £18,000, but that figure had gradually advanced to £61,500, and he saw no reason why it should not continue to have an upward tendency.

The report was adopted unanimously.

SOUTH AMERICAN LIGHT & POWER CO.—The net profit for the year ended March 31, was, including £558 brought forward, £10,037. The directors recommend payment of a dividend of 5 per cent. on £150,000 capital and also payment of interest at the rate of 5 per cent. on the £71,380 capital expenditure incurred during the year by the railway company; leaving £1,080, of which £500 is to be placed to reserve, and £580 carried forward.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES, &c.

NEW COMPANIES.

ALDEBURGH ELECTRIC SUPPLY CO. (LTD.) (116,867)—*Reg.* July 18, capital £7,000 in £1 shares, to manufacture and supply electricity in Aldeburgh, Suffolk, and neighbourhood, and to adopt an agreement with Christy Brothers & Co. (Ltd.). *First* directors: W. H. Hall, G. O. Knowles, W. Hill, L. F. Christy and F. Christy. Reg. office: 177, High-street, Aldeburgh.

ALEXANDER HARVEY EXPLOITATIONS (LTD.) (116,852)—Reg. July 7, capital £6,000 in £1 shares, to carry on the business of electricians, mechanical engineers, suppliers of electricity, &c., and to adopt an agreement with H. A. Harvey, G. P. M. Lee and C. A. Owen. Private company. First directors: H. A. Harvey, G. P. M. Lee, Q. Marino and C. A. Owen. Reg. office: Norfolk House, Laurence Pountney-hill, London, E.C.

SAN LUIS (MEXICO) TRAMWAYS (LTD.) (116,808.)—Reg. July 13th, capital £150,000 in £1 shares, to construct, purchase, lease, or otherwise acquire, sell, grant leases of, use or work any tramways, railways, &c., to generate, purchase and supply electricity, &c.

C. S. WILSON & CO. (LTD.) (116,870)—Reg. July 18, capital £5,000 in £1 shares, to carry on the business of manufacturing, supplying and laying "Litosilo" and other compositions, engineers, electricians, &c., *to acquire* the business carried on by G. Harding at Liverpool as C. S. Wilson & Co. Private company. G. Harding is managing director.

STATUTORY RETURN.

BARNSLEY & DISTRICT ELECTRIC TRACTION CO. (LTD.)—Return to June 6 gives capital as £50,000 in £5 shares (5,000 preference). 4,400 preference and 4,007 ordinary shares taken up. £5 per share called up. £42,035 paid. Mortgages and charges: £21,000.

BIRKDALE DISTRICT ELECTRIC SUPPLY CO. (LTD.)—In return to May 29 capital is £30,000 in £5 shares. All shares taken up and paid for in full. Mortgages and charges: £3,000.

BRITISH WESTINGHOUSE ELECTRIC & MFG. CO. (LTD.)—Return dated May 15. The capital is £1,875,000 in 500,000 £3 preference shares and 75,000 £5 ordinary shares. (Original capital: £1,500,000 in 200,000 £5 preference shares and 50,000 £10 ordinary shares.) All shares taken up. £3 per share called up on 500,000. £1,500,000 paid. £375,000 considered as paid on 75,000 shares. Mortgages and charges: £1,474,953.

MORTGAGES AND CHARGES.

LODGE-MUIRHEAD WIRELESS & GENERAL TELEGRAPHY SYND. (LTD.)—Issue on July 14 of £2,000 debentures, part of a series of which particulars have already been filed.

REASON MFG. CO. (LTD.)—Mortgage dated July 4, to secure £1,000 and certain costs, &c., charged on present and future indebtedness to the company of Motor Meters (Ltd.) and of the Municipal Corporation of Stepney. Holders: Barclay & Co. (Ltd.)

O. RUHL (LTD.)—Memorandum of satisfaction in full on July 4 of debentures dated Nov. 5, 1909, securing £800, has been filed.

"Z" ELECTRIC LAMP MFG. CO. (LTD.)—Floating charge on stock of manufactured lamps for time being at factory at Southfields, dated June 27, to secure moneys to extent of £9,500, which the mortgagees (as guarantors) may become liable. Holders: Kilburn, Brown & Co.

RECEIVERSHIPS.

BROCKIE-PELL ARC LAMP (LTD.)—R. Warner, of 10, Walbrook, E.C., ceased to act as receiver or manager on July 1.

CONSOLIDATED ELECTRIC WORKS AND APPLIANCES (LTD.)—Notice of the appointment of J. W. M. Harling, 73, Fairbridge-road, Upper Holloway, N., as receiver or manager, has been filed. (Notified July 10, 1911.)

C. PENTON LINDOP (LTD.)—Notice of the appointment of F. T. P. Deyes, 5, Cook-street, Liverpool, as receiver or manager, by order of court dated July 3, 1911, has been filed.

KIRLEW BROS. (LTD.)—Notice of the appointment of A. Whale, Bishopsgate House, London, E.C., as receiver and manager, by order of court dated July 14, has been filed.

NORFOLK ELECTRICAL CO. (LTD)—G. E. Ridsdale, Winchester House, Victoria-square, Birmingham, ceased to act as receiver or manager on July 8, 1911.

CITY NOTES.

MEMORANDA (July 27th.—**Bank rate 3 per cent. (March 9, 1911.) Price of silver, 24⅛d. per oz. Consols 78⅛—78⅜ for money and for account. Consols Pay Day, Aug. 2; Stock and Shares Continuation Days, Aug. 14 and 29; Ticket Days, Aug. 15 and 30; Pay Days, July 28 and Aug. 16; Mining Shares Carry Over Day, Aug. 11.**

PRICES OF METALS (London).—***Copper*, cash, 56⅜; three months, 56⅜.** ***Lead*, English, 14⅛—14⅜; Foreign, cash, 13⅞, three months, 14.** ***Spelter*, 25—25⅛.** ***Tin*, English, 192—194; Foreign, cash, 191½; three months, 186¾.** ***Iron*, Cleveland, cash, 46/10, three months, 47/6½.**

BAHIA TRAMWAY, LIGHT & POWER CO.—The earnings of this Company in June were £12,933 (increase £2,066). Aggregate from Jan. 1, £76,933 (increase £13,238).

CALCUTTA ELECTRIC SUPPLY CORPN. (LTD.)—The number of units delivered to consumers during the four weeks ended May 26 were 831,872, compared with 786,249 units in the corresponding four weeks of 1910.

CHELSEA ELECTRICITY SUPPLY CO. (LTD.)—The directors have declared an interim dividend at the rate of 4 per cent. per annum (2s. per share) on the ordinary shares for the half year to June 30.

CITY OF BUENOS AYRES TRAMWAYS CO.—A dividend of 1s. 3d. per share, less tax, for the three months ended June 30 is announced.

COMPANIES TO BE STRUCK OFF THE REGISTER.—The following will be struck off the register of Joint Stock Companies unless cause to the contrary is shown before Oct. 21.

Formby & Freshfield Electric Light Co., Macclesfield Electric Lighting & Power Co., Penarth Tramway Synd., Phœnix Electric Heating Co.

COUNTY OF LONDON ELECTRIC SUPPLY CO. (LTD.)—The directors have declared interim dividends for the half-year ended June 30 at the rate of 6 per cent. per annum, less tax, on the preference and at the rate of 4 per cent. per annum, less tax, on the ordinary shares, payable Aug. 5. The transfer books and register of members are closed from July 25 to Aug. 4, inclusive.

LLANELLY & DISTRICT ELECTRIC LIGHTING & TRACTION CO. LTD.—This company is making an issue of £50,000 5 per cent. first mortgage debenture stock at par. The subscription list closes to-day (Friday).

MONTREAL LIGHT, HEAT, & POWER CO.—The directors have declared a dividend of 2 per cent. on the paid-up capital (being at rate of 8 per cent per annum) for quarter ending 31st inst.

The directors have decided to make an all-round reduction in their charges, the change to take effect as from the commencement of this month. In the case of domestic consumers the reduction amounts to 6¼ per cent., while for industrial enterprises the alteration is equivalent to a saving of 16⅔ per cent.

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY CO. (LTD.)—An interim ordinary dividend of 2 per cent. is announced.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed Aug. 3 a special settling day in Speyer Bros.' scrip certificate (fully and partly paid) for £1,538,700 joint power house rent charge stock of the *Metropolitan District* and *London Electric Railways*, and fully and partly paid scrip for $3,500,000 first mortgage 5 per cent. 40-year gold bonds of the *Mississippi River Power Co.*, and have ordered both to be quoted. Quotations have also been granted to $4,899,000 5 per cent bonds (1925) of the *Bell Telephone Co. of Canada (Ltd.)*, a further issue of £200,000 deferred ordinary, £200,000 preferred ordinary and £200,000 5 per cent. cumulative perpetual preference stock of the *British Columbia Electric Railway Co. (Ltd.)*, and $5,664,200 additional common stock of the *Mexico Tramways Co.* The Committee have been asked to grant a quotation to a further issue of 22,000 £5 fully paid shares of the *Chili Telephone Co. (Ltd.)*.

TUBE AMALGAMATION.—An important amalgamation of Scottish producers of wrought iron and steel tubes has been effected after lengthy negotiations. The companies concerned are as follows:—Scottish Tube Co. (Ltd.), Wilson's & Union Tube Co. (Ltd.), David Richmond & Co. (Ltd.), Hendry Bros. (Ltd.), David Marshall & Sons, James Edie & Sons, Caledonian Co., Coats Tube Co., and the Tradeston Tube Co. Messrs. Stewarts & Lloyd (Ltd.), the leading firm in this country in this line, are not parties to the amalgamation, but are stated to be working in harmony with the new combine. The combination is wholly the outcome of the ruinous cutting of prices which has prevailed over the past three years in this branch of industry.

WEST INDIA & PANAMA TELEGRAPH CO.—A statement having appeared in one of the financial papers that the American Government in acquiring control of the West India and Panama Telegraph Co., Mr. R. P. Brown, manager and secretary of the company, has issued an emphatic denial of any truth in the statement so published.

NOTES.

Metallic Conductors without Resistance.

A most important experimental confirmation of the theory that at the absolute zero of temperature certain metals possess an infinite conductivity has just been announced by Prof. H. Kamerlingh Onnes, an abstract of whose Papers dealing with the subject appears elsewhere in this issue. The resistivity of metals is one of the physical properties which appeal very strongly to the electrical engineer, since it is of great practical importance in his work. The experimental results obtained by Prof. Onnes a few years ago, when he examined the behaviour of pure gold down to temperatures as low as −262°C., though affording proof that the resistivity continued to decrease as the temperature diminished, did not indicate at all clearly that zero resistance would be reached, seeing that at this very low temperature, only 11 deg. from the absolute zero, the resistance had merely fallen to one four hundredth of the resistance at 0°C., while in the case of mercury the resistance at −258·8 deg. C. was as much as $\frac{1}{1\,2\,9}$th of the resistance at 0°C. Since then, by the exercise of great care and improvement in experimental detail, together with the use of liquid helium, the lowest temperature reached has been pushed still further towards the absolute zero; and at 3°K., that is, 3 deg. on the Krypton thermometer, the resistance of a column of mercury has been found, by several different electrical methods, to be less than *one ten-millionth* of the resistance which it had at 0°C.

It can hardly as yet be realised what this result means to physical science, and to electrical science in particular. An almost limitless field of new experimental research is opened up, while many older problems can be re-attacked with greater probability of success. It is indeed a fascinating idea to think of working with an electrical conductor which has no such property as resistance. Prof. Onnes points out that films of metal of molecular thickness could be employed, and heavy currents could be carried by these without any heating occurring. Many other uses suggest themselves; for instance, solenoids of fine wire could be employed with enormous currents, and in this way magnetic fields greatly surpassing in intensity any which have been obtained hitherto will be realisable. On the other hand, there will be effects obtained, due to this practically infinite conductivity, which will be equally interesting to observe, though of less importance. One of these is the production of eddy currents in a mass of metal. Where the conductivity is so excessively high it is obvious that, even when any change in the current is made exceedingly slowly, there will be an enormously increased effect produced by the minute E.M.F.'s set up by the change. The number of examples could be extended indefinitely, but enough has been said to show that we are on the threshhold of a quite new, and we believe fruitful, field of research.

The Ways of Municipalities.

We fear that the impression will soon be current that municipalities have no conscience, whatever other virtues they may possess. Last week the West Hartlepool Corporation appealed against a judgment in regard to the West Hartlepool tramways. Some little time ago the Corporation exercised their option to purchase, and agreed to pay the sum of £12,963 which had been fixed by the arbitrator as the value of the undertaking. Subsequently it seems, however, the Corporation discovered some slight

Digitized by Google

irregularity in the legal position of the Tramways Company and then saw that there might be some ground on which only part of the undertaking need be purchased; in other words, they saw a chance of getting the tramways at a very much reduced price owing to a possible legal technicality in regard to the title. The original action was given against the Corporation, but they thought fit to appeal. During the appeal Lord Justice BUCKLEY asked whether they wished to get out of their bargain, and the reply to this was that the Corporation wished the Company to get out of the streets because they were trespassers. To the lay mind this seems a little difficult, but counsel suggested that they could take their tramways away with them. Lord Justice VAUGHAN-WILLIAMS very pertinently remarked that it was the duty of a public body to act reasonably in the public interest, and Lord Justice FLETCHER MOULTON remarked that it really was scandalous that because the Company had made some irregularity in the formal transfer the Corporation should suggest that they had the power to take the undertaking and not to pay anything for it.

WE are glad to see that the appeal failed, for it appears to us that public bodies, such as municipalities, have a very distinct duty to the public at large. If such bodies have no sense of equity and are prepared to indulge in what is, to all intents and purposes, robbery when so permitted by legal technicalities, then the private individual who has not a sufficiently long purse to fight in such matters will very soon come off badly. Indeed, there is an increasing feeling at the present time that the interests of the private individual are by no means safeguarded when he is dealing with public bodies, and this is a feeling which is unfortunate from every point of view.

Electricity in Textile Mills.

THE problem of how best to apply the electric motor to the driving of textile machinery is one that still awaits a full and sufficient solution. This is to some extent, we think, due to the fact that many of the underlying peculiarities of this class of machinery are not fully grasped by those responsible for designing the motor. The mill is one of those places that require special treatment; it is not, for instance, sufficient just to put down a motor and connect it up to the looms by belt or direct. Further, we cannot help thinking that the report of the Bradford Engineering Society, published rather less than two years ago, had a detrimental effect on the progress of the electric drive. The report, it will be remembered, was not altogether favourable to the motor, and the feeling of uncertainty was further increased by the aspersions cast on the actions of the Committee by several of its members. At the time we said: "We think that the report is a move in the right direction, but we cannot help feeling that the Committee have not gone into the matter far enough, and we hope the question of individual drive will be considered in a later report."

SINCE that date very little has been done by any properly constituted body, though the introduction of the electric motor into textile mills has been making as satisfactory progress as could perhaps be expected. Now, however, as will be seen by reference to the next column, a further attempt is to be made to solve the question of the suitability of various forms of driving for mill work. A Joint Committee has been appointed, consisting of 14 members of the Textile Institute and 14 members of the Institution of Electrical Engineers, the latter being mainly drawn from the Lancashire and Yorkshire districts. Mr. THOMAS ROBERTS, of Darwen, a prominent cotton manufacturer, is the chairman, and Mr. S. L. PEARCE is the vice-chairman. We are pleased to note that experiments are to be made with the various forms of drive proposed, and it is to be hoped that, as a result, some conclusive data will be obtained. The deliberations should result further in an increase of mutual knowledge among the various members of the Committee, a state of things which is always greatly to be desired.

Rating of Telephone Property.—It is stated that Dundee Council have raised the question whether the Government should make provision, in the Telephone Transfer Bill or otherwise, to compensate local authorities for the loss of rates hitherto paid by the National Telephone Co., as such payments will cease automatically when the telephones become Crown property. In Dundee the valuation upon which such rates are payable is £5,682.

Applications for Extension of Patent.—A petition will be heard on or after November 27th for extension of the term of patents numbered 1,020 and 1,022 of 1898, granted to Chas. Hy. Stearn for "Improvements in the manufacture and production of a filamentary material and fabrics therefrom" and "Improvements in the manufacture and production of a material in film sheet or web form." The High Court has fixed November 20, 1911, as the day on or after which the petition of the Automatic Electric Co., of Chicago, for the extension of the term of Letters Patent No. 809/1898, will be heard.

Electricity in Textile Mills.—According to our Manchester contemporaries a meeting of representatives of the Textile Institute and of the Institution of Electrical Engineers was held at the Textile Institute, Manchester, on Friday last, to consider the question of conducting an investigation into the application of electricity in textile mills, both in the United Kingdom and abroad.

After discussion it was decided to form a joint committee to be known as the "Textile Mill-driving Committee," the committee to consist of 14 representatives of the Textile Institute and a similar number of representatives of the Institution of Electrical Engineers. Mr. Thomas Roberts, cotton manufacturer, Darwen, was unanimously elected chairman of the committee and Mr. S. L. Pearce, Manchester city electrical engineer, vice-chairman. The members of the committee elected were as follows:—*Textile Institute representatives:* Messrs. J. R. Denison (Messrs. Denison, Preusner & Co.), Bradford; B. Palin Dobson (Messrs. Dobson & Barlow), Bolton; E. P. Fry, of Shipley, Yorkshire; Oscar Hall (Messrs. Robert Hall & Sons), Bury; Frederick Leeves (Messrs. Platt Bros. & Co.), Oldham; Frederick Lye (Messrs. John Bright & Bros., Rochdale; F. Nasmith (Messrs. Nasmith & Barraclough), Manchester; W. J. Orr (Messrs. Orr & Sons), Castleton, Rochdale; Thomas Robert (Messrs. Whipp Bros. & Co.), Darwen; Fletcher Robinson, of Manchester; George B. Storie, of Rochdale; F. W. Whittaker (Messrs. Whittaker & Pendlebury), Bradford; and T. Rowland Wollaston, of Manchester. *Electrical Engineer representatives:* Messrs. H. Dickinson, R. K. Morcom, A. B. Mountain, S. L. Pearce, J. S. Peck, W. N. Rogerson, J. Schofield, J. F. C. Snell, C. D. Taite, S. J. Watson, H. Wilson, W. B. Woodhouse, Dr. R. Pohl and Prof. Schwartz.

There had been, it was pointed out, previous attempts to make investigations into the relative merits of electricity, steam, gas, &c., for motive power, but there had been no such representative committee appointed to examine into the question as that now brought together. The investigation which the joint committee proposes to conduct will be thoroughly exhaustive in character. It will not be a matter altogether of receiving evidence, but experiments will be carried out with the object of making the final report of real value to everybody concerned in the question of power supply.

Cable Interruptions.

	Date of Interruption
Assab—Perim	July 8, 1909
Latakia—Palura	May 26, 1910
Zanzibar—Mombasa	July 11, 1911
Guam—Manila	July 12, 1911
Cayenne—Salinas	July 29, 1911

Diesel Locomotive for Prussian State Railways.—It is stated from Berlin that a 1,000 H.P. locomotive driven by a Diesel engine has just been set to work on the Prussian State Railways. The drive is direct to the axles and the outward appearance is similar to that on an electric locomotive. Nearly £12,000 has been spent in experimenting with this engine.

Employment of Electrically-worked Street Washers.—According to the "Commercial Motor," since the municipality of Schönberg, near Berlin, took over the duty of keeping the streets clean steady progress has been made in the direction of mechanical propulsion. Within the next few weeks the borough will possess a dozen electrically-driven street washers, and the year 1912 is to see all horse-drawn dust carts, street sweepers and water carts replaced by the mechanical type. A special depôt is being constructed for the housing of these automobiles.

The Manufacture of Nitrates in Italy.—According to "The Times" Engineering Supplement, for some time past experiments have been in progress at Legnano with the object of utilising the excess power generated during the night and certain hours of the day by a large hydro-electric station. The aim was to produce nitric acid and nitrates from the nitrogen of the air, and it is considered that the problem has now been satisfactorily solved. Some months ago the employment of 4,000 kw. for the production of nitric acid was initiated, and now preparations are being made for the use of 9,000 kw. more, energy being supplied by the Società Lombarda per Distribuzione dell' Energia Elettrica at a pressure of 50,000 volts.

The German Wire Industry.—"The Engineer" states that the convention between German manufacturers of wire and kindred goods, the formation of which was beset by many difficulties, has collapsed, and ceased its functions at the end of June, the members being now free to contract for sales for delivery. This result is regretted by many of its members, as the convention worked fairly satisfactorily. The stumbling block in the way of a renewal of the union was the absolute refusal of several works to submit to any limitation as to production. This, on the other hand, was insisted upon, as far as the large manufacturers were concerned, as a mere price agreement handicaps certain works. Of late there had also been certain price reductions which were at variance with the agreement. The cessation of the convention will probably have an unfavourable effect upon works which make wire rods.

35-ton Slow Speed Electric Locomotive.—According to the "Electric Railway Journal" the Woodward (Ala.) Iron Works have ordered a 35-ton low speed locomotive from the General Electric Co. It will be used for hauling coke. The locomotive will make about 50 trips a day, the approximate length of each trip being 2,000 ft., and it will handle 20 tons of coke per trip. There is a 3 per cent. gradient about 300 ft. long. The locomotive has an all-steel frame and cab, and an arch bar truck. It is equipped with single unit control. Current is supplied at 220 volts. The motor equipment consists of four motors furnished with gearing giving a ratio of 4·25 to 1. The motors can develop a tractive effort of 10,000 lb. at the rated one-hour load with a speed of six miles per hour. A bow trolley on the cab roof will make contact with a trolley wire having a variation in height from 15 ft. to 22 ft. above the rail heads. The fuse box and lightning arrester are also mounted on the cab roof.

Crystal Palace School of Engineering.—The terminal award of certificates and prizes at this school took place on Wednesday last, when Major Sir T. B. Robinson, Agent-General for Queensland, presided in the absence of Sir A. Fitzroy. Sir Thomas said there was plenty of room in Queensland for the engineer and he trusted that some day-students of that school would find it a profitable field for their energies. There were still questions awaiting solution by engineers. These included the discovery of improvements in the methods of propelling ships, while the development of the oil engine offered a wide field for men with brains. Another branch of work which deserved great attention was the improvement of workmen's tools. In conclusion, he gave some advice to students. It was really astonishing, he said, what duffers could do if they only stuck to it. It was his advice to duffers, among whom he reckoned himself, that all their difficulties would yield to persistent effort. It was the fellow who did everything a little more thoroughly and more quickly than other people who went ahead. The certificate of honour was awarded to Mr. J. M. S. Trelawney.

United States Government Control of Electricity in Mines.—An electrical section of the Bureau of Mines in the United States was organised in 1909 to investigate the conditions under which electricity is used underground, and to obtain data which would be of assistance to state officials who had charge of the regulation and inspection of mines, and also to those who used or manufactured electrical mining equipment. This section is part of the mining experimental station of the Bureau at Pittsburgh. Technical paper No. 4, issued by the Bureau of Mines, sets forth in detail the purposes and equipment of the section, and gives an account of some of its work. Preliminary investigations on incandescent lamps were made, which showed that certain sizes of lamps when broken ignite surrounding explosive mixtures of gas and air, and tests are now being made to determine the factor of safety of such lamps as have not caused ignition in previous experiments. An investigation is also being carried on relating to the action of acid mine water upon the insulation of electrical conductors. Tests have recently been finished of electric fuses with relation to their use in mines. Seven different types of enclosed fuses were tested by being mounted in standard clips or holders and placed inside a gas-tight, boiler-iron box, which was provided with means of admitting gas of any desired composition. The results of the tests were as follows:—(1) One or more sizes of all the brands of fuses tested ignited the gas, although in varying degrees. Two brands ignited the gas at once; three brands ignited it in more than 50 per cent. of the tests. (2) The principal sources of danger in fuses as they are now designed is the device for indicating whether or not a fuse has acted. (3) Danger from blowing at the relief ports will probably develop in some, and possibly in all, brands if tested with sufficient current.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

In an article on the "Hunting of Direct-current Interpole Motors" Dr. E. Rosenberg discusses in detail the effect of brush currents on the field of a motor, and their tendency to cause hunting.

In a Paper, of which we give an abstract, read before the Institution of Mechanical Engineers, Mr. E. Huber-Stockar gives an account of the present position of electric traction in Switzerland.

At the same meeting Mr. H. Zoelly read a Paper, of which we give an abstract, describing the development of that type of steam turbine which bears his name.

We conclude our description of the electrical equipment of ss. "Olympic" and "Titanic."

Prof. H. Kamerlingh Onnes has recently conducted some researches into the resistance of metals at the temperature of liquid helium. The results of these researches are given in this issue, and are notable for the fact that figures closely approaching zero resistivity were obtained.

Mr. F. Schubeler, in a Paper (of which we give an abstract) read at the recent meeting of the Institution of Mechanical Engineers, deals with the design of Diesel engines for various classes of work.

A single-phase locomotive which has been built by the A.E.G. for the Midi Railway of France is described.

Details are given of the electrical equipment at the Sneyd Colliery, Burslem.

A meeting of the Miners' International Association was held last week, when Mr. Albert Stanley, M.P., returned to his attack on the employment of electricity in mines. Mr. Stanley has a somewhat lurid vocabulary. He described electricity as "That new, weird and intangible, but very terrible factor," and in another part of his remarks as "that new and terrible agent." His hearers must have felt their very blood curdle.

Digitized by Google

An abstract is given of the accounts of the L.C.C. tramways for the year ended March 31.

Legal.—On Monday Mr. Justice Swinfen Eady delivered judgment in the action brought by the Thermal Synd. (Ltd.) against Silicaware (Ltd.) for an injunction to restrain an infringement of letters patent relating to the working of silica. His lordship held that plaintiff's patent was valid, and he granted an injunction.

Companies' Meetings, Reports, &c.—At the meeting of the London, Brighton & South Coast Railway Co. on Wednesday Mr. C. Macrae stated that the results of the electrical working had been very satisfactory and that the number of passengers carried was increasingly steadily.

Particulars are given of the proposals for the re-arrangement of the capital of the British Electric Traction Co.

PERSONAL NOTE.

Prof. S. P. Thompson, F.R.S., has left London for Germany to represent the Royal Society at the centenary celebrations of the University of Breslau.

APPOINTMENTS VACANT AND FILLED.

The Borough of Aston Manor Education Committee require an assistant master qualified to teach electrical and mechanical engineering and mathematics (especially practical). Duties to begin Sept. 18. Commencing salary £160. Applications to Mr. H. Norwood, Director of Education, Education Offices, Aston Manor, near Birmingham, by Aug. 28. See also an advertisement.

Applications are invited for the post of assistant to the wireless telegraph expert on H.M.S. "Vernon," Portsmouth. The appointment will be for three years. Salary £300 per annum. Applications to the Secretary of the Admiralty, Whitehall, London, S.W. See also an advertisement.

An electrical fitter is required for Gold Coast Government Waterworks. Salary £300, rising to £350 by annual increments of £10. Applications to the consulting engineers, Messrs. Middleton, Hunter & Duff, 17, Victoria-street, London, S.W. See advertisement.

A demonstrator or assistant lecturer is required in the Physical Laboratory of University College, Reading. Commencing salary £125. Particulars from the Registrar. Applications by Aug. 28.

A chief assistant electrical engineer is wanted for Batley electricity works. Salary £130. Applications to the Town Clerk by Aug. 9.

The Rochester, Chatham and Gillingham Joint Higher Education Sub-Committee require a lecturer for engineering subjects. Commencing salary £150. Forms of application from Mr. R. L. Wills, M.A., 2, Military-road, Chatham, to whom applications by Aug. 9.

Dundalk Urban Council have appointed Mr. Percy A. Spalding, A.M.I.C.E., A.M.I.E.E., of Galway, out of 93 applicants, as resident engineer of their electricity undertaking, at a salary of £250 per annum. Mr. Spalding will act as clerk of works during the erection and equipment of the works, for which a loan of £20,000 has been obtained. Mr. Spalding was selected by the Council by 10 votes to 2.

Mr. Geo. Hy. Woollatt, principal of the Victoria Science and Technical Schools, Worcester, has been appointed (out of 75 applicants) head master of the new Workington Technical College, at a salary of £500 per annum.

Dr. Ing. M. Kloss, M.I.E.E., of Siemens Bros. Dynamo Works, Stafford, has been appointed professor of electrical engineering at the Technical University, Berlin-Charlottenburg.

Southampton Council have appointed Mr. A. Bennett, of the Westminster Electric Supply Corpn., as commercial engineer, or head of the business development department of the electricity undertaking at a salary of £225 per annum, rising at the end of 12 months to £250 per annum.

INSTITUTIONS AND SOCIETIES.

National Electric Light Association.—It is stated that the date for the next convention has been fixed for June 10 to 14, 1912. The meeting will be held at Seattle.

EDUCATIONAL NOTICES.

University of London.—In the faculty of engineering at University College an entrance scholarship, value 120 guineas, instituted by a fellow of the college, will be competed for in September. Candidates must have passed the University of London matriculation, or an examination accepted in lieu thereof.

The post-graduate courses for next session, which will commence on Monday, Oct. 2, will include: "The Photomicrographic Study of Metals," by Mr. F. Bacon; "The Design and Calculation of Aeroplanes," by Mr. A. R. Low; "Steam Turbines," by Mr. W. J. Goudie; and "Some Modern Methods in the Design of Structures," by Mr. H. P. Philpot.

University of Sheffield.—The faculty of applied science comprises the departments of engineering, metallurgy, coal mining and architecture. The courses in engineering or in metallurgy extend over three years and prepare respectively for the degree of B.Eng. or B.Met. of the university. The lecture courses commence on Oct. 4, and the technical laboratory courses on Sept. 18. Prospectuses and other particulars from the registrar, Mr. W. M. Gibbons.

University of Durham.—Armstrong College, Newcastle-upon-Tyne.—The 1911-12 session commences Sept. 25. There are departments of mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars may be obtained from the secretary, Mr. F. H. Pruen, M.A.

University of Bristol.—The results of the examinations for the degrees and certificates in the faculty of engineering at this university are as follows:—

M.Sc., A. J. Margetson. B.Sc., C. E. Holloway and A. J. S. Pippard (first class honours in Civil Engineering); J. N. B. Bhaskar and T. H. P. Veal (second class honours in civil engineering); R. Woodward (2nd class honours in mechanical engineering); W. C. Batta, W. G. Came, N. L. Mehta, G. M. Sury and A. W. Thomas (pass degree in civil engineering) J. W. Burrough and L. G. Parkinson in mechancial engineering, and C. G. Bevan and E. J. Hamlin in electrical engineering. University certificates in civil engineering were granted to two students, in mechanical engineering to one, in electrical engineering to two, and in motor car engineering to one student.

City and Guilds (Engineering) College.—This college, which was formerly known as the Central Technical College of the City and Guilds of London Institute, forms the engineering section of the Imperial College of Science and Technology. The courses of instruction in civil and mechanical engineering are conducted by or under the supervision of Prof. W. E. Dalby and those in electrical engineering are under Prof. T. Mather.

The courses of instruction include (*a*) diploma courses for the Associateship of the City and Guilds of London Institute in civil and mechanical and electrical engineering; (*b*) special or partial courses for a limited number of students whose knowledge and experience enable them to engage in research work or to omit part of the regular diploma courses; and (*c*) advanced specialised courses for post-graduate and other duly qualified students. Prospectuses which contain full particulars of the entrance examination and courses of instruction, scholarships and fees may be obtained from the Secretary of the College, Exhibition-road, London, S.W.

City and Guilds Technical College.—This college provides a scientific training for students preparing to become electrical and mechanical engineers or chemists, and for engineering pupils who desire to supplement their practical training by a two years' course of instruction in the principles of engineering science. There are also arrangements for three-year courses in engineering. Particulars at the college, Leonard-street, City-road, London, E.C., or from the City and Guilds of London Institute, Gresham College, Basinghall-street, London, E.C.

Brighton Municipal Technical College.—Two students (W. W. Stainer and C. L. Weiss) of this college, who have this session been attending the third year engineering day course, have passed the Examination of the London University for the degree of B.Sc. in the faculty of Engineering.

Mr. Stainer, who is not yet 19 years of age, is the son of the head-master of the Municipal Secondary School (Mr. J. Stainer, B.A.) and received the whole of his education in Brighton, passing the matriculation and intermediate science examinations from the Secondary School, and the intermediate engineering last year at the Technical College. Mr. C. L. Weiss is 19 years of age, and was educated privately and attended evening classes at the Technical College for the intermediate engineering examination, which he passed in 1910, since when he has been a full time day student at the College.

ARRANGEMENTS FOR THE WEEK.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued:—

Head-quarters will be closed for instruction, but will be open for office work as under until further orders:—

Monday to Friday, 10 a.m. to 4 p.m.

Saturday, 10 a.m. to 12 noon.

ELECTRIC TRACTION IN SWITZERLAND.*

BY E. HUBER-STOCKAR
(Of Zurich).

Summary.—The author deals with the reasons why electric traction has not made so much progress in Switzerland as would have been expected, seeing that this was one of the earliest countries to adopt electric locomotion. He also gives full details of the various railways at present being electrically worked in Switzerland and finally of two schemes that have been prepared for the electrical operation of the St. Gothard Railway.

The reason for dealing more particularly with railway electrification in Switzerland is not because great progress has been made in that country, but because of the more general interest it presents in comparison with many other countries. First of all, it may be astonishing that progress has not been greater than it actually has been, when one considers that Switzerland has to buy all its coal from foreign countries and has a large amount of water-power still waiting for utilisation.

Secondly, Switzerland electrified certain railways at a comparatively early date, and might be expected to have gone onward on this basis, especially as applied electricity is highly developed in the country generally.

Thirdly, the very reason of the progress being less than may be expected adds greatly to the interest of the problem as presented in Switzerland. There are no such sections of railways as the terminal section of the New York Central and Hudson River and the New York, New Haven & Hartford Railways, where steam has played out its rôle on account of the frequency of the trains or the smoke nuisance, and no such sections as the London Bridge and Victoria line of the London, Brighton & South Coast Railway, where over a million passengers were recovered that had been better served by competing tube and street railways. Though railway electrification in Switzerland is inseparable from the use of water-power, and though this use is evidently beneficial to the financial situation of the country in the long run, still it must, for various reasons, be done in such a way as not to disturb the balance of traffic receipts on the one hand and the operating expenses and interests on loans on the other. The time is still far distant when even State railways are built, as the principal roads have been built all through the country and over the mountain passes, simply because they are necessary, no matter whether they are remunerative or not. Railways are still built and operated for the greater part, and most fortunately so, even by the State, on the basis of commercial enterprise. Therefore, more particularly in Switzerland, where railways are, on the whole, not making profits because of cost of construction, heavy gradients, rather irregular traffic, short average distance of travel, high wages, low fares and so on, the problem of railway electrification is in every case a problem mainly of general economics of railway operation, since the technical problem has admittedly been satisfactorily solved.

The electrifications of importance that have hitherto been or are being carried out are almost all either of an experimental or preparatory character, or were brought about by considerations not directly or purely economical. In Switzerland the economy of operation is having decisive weight and makes the problem difficult, while, as in other countries, the railways already electrified, or about to be electrified in the near future, are such that the smoke nuisance would render steam working almost prohibitive, as in the case of the Simplon tunnel, or where the capabilities of steam are nearly exhausted, as in the case of the St. Gothard railway.

The author then describes in detail several typical Swiss railways which are electrically worked. These include the Burgsdorf-Thun line which was the first railway of any importance to use three-phase current. The energy consumption on this line is 68 watts per ton-kilometre (109 watts per ton-mile). Another interesting line is the Freiburg-Murton-Ins Railway, which was the first normal gauge railway to undergo electrification and the only normal gauge line in Switzerland to be carried out on the continuous-current system with third rail. A pressure of 500 volts is used. The consumption is about 34 watts per ton-kilometre (57 watts per ton-mile), exclusive of losses in the converting machinery and batteries. The Simplon tunnel, Seebach-Wettingen, Seetal and the Martigny-Orsières lines, details of all of which have from time to time appeared in THE ELECTRICIAN, are next described in detail. Some figures with regard to these systems are given in the accompanying tables.

The author next describes the Bern-Lötschberg-Simplon (B.L.S.) Railway, which will give direct access to the Simplon tunnel from the north-west of Switzerland. It will be of prime importance to international traffic, as it considerably shortens the distance between certain important places and Milan.

The new railway is noted for its tunnel under the northern main range of the high Alps. It is still in course of construction, and will be opened probably within about two years from now. Its length is 60·4 km. (97 miles), and it will resemble the St. Gothard railway a good deal in general character. The smoke from steam locomotives would, as it does on the St. Gothard, interfere with the comfort of travellers, and inconvenience the operation. Electric traction has therefore been, from the very beginning, a *sine qua non* with the B.L.S. Co.

The access to the northern end of the new railway from the system of main lines is a railway from Spiez, on the Lake of Thun, to Frutigen, 13·4 km. (21 miles) long and operated by steam since 1901. This railway will be or has already been absorbed, and has been equipped electrically by the B.L.S. After careful consideration, single-phase traction with high voltage (15,000) and low frequency (15) was adopted, and towards the end of 1908 orders were placed for equipment. The electrification of this short line of access was undertaken as an experiment, and was completed at the end of 1910. The success of this electrification has been such that it will be extended to the whole line and on the same system. For this reason, the Spiez-Frutigen electrification deserves special consideration as the first section of a main-line railway which furnishes in certain respects exactly the problem of the St. Gothard electrification, namely, long heavy gradients of 2·7 per cent., and heavy trains requiring 2,000 H.P. and more to drive them.

The load on the power stations will be of a similar character to that of the St. Gothard railway, with reference to which some remarks will be made later.

The energy for the present service on the Spiez–Frutigen line is supplied from the Bernische Kraftwerke company's works near Spiez. Here there are, for the special purpose of the Spiez-Frutigen system, two hydro-electric sets of 3,200 H.P. each, generating single-phase alternating current at a voltage of 16,000 and a frequency of 15, that is to say, a current which requires no further transformation nor conversion to suit directly the motor cars and locomotive equipments.

The power supply from the Kanderwerk is but temporary. The Bernische Kraftwerke have started the operation of a new power station at Kandergrund, a place situate near the B.L.S. Railway, not far from its centre of maximum power demand on the northern slope. In the future, therefore, the supply of power to this part of the line will be from this station, and the southern slope will be supplied from another company's works on the rivers Rhône or Lonza.

The overhead line is of the most substantial design, all the supports being of steel. The devices for regulating the supply of current to the individual sections of the line or railway stations, the devices for protection from lightning and the instruments for measuring or electrical supervision purposes are very complete, in a style that may appear luxurious in comparison with most other electric railways, but is, in reality, only up to the general installation standard on main-line railways. The driving equipment consists of three motor cars and two locomotives, one of 2,000 H.P. and the other of 1,600 H.P. capacity. The contacts are of the pantograph pattern and are capble of self-adjustment between heights of 4·8 m. and 7·05 m (16 ft. to 23 ft.).

The large gears of the 2,000 H.P. locomotive are novel. They are of the **N** spiral type, the pitch circle diameters being 1,453 mm. and 447 mm. (5 ft. and 17·8 in.). They are automatically machine cut, and run without noise and vibration. They engage with each other on surfaces much in excess of those of any other type of gear wheels, and run at a circumferential speed of 22 m. (72 ft.) per second. The maximum surface-pressure on the teeth is 260 kg. per sq. cm. (3,800 lb. per sq. in.).

The Oerlikon locomotive nearly reaches that limit where the use of gearing affords a decided advantage over connecting rods direct from the motor. Such gearing does away with all reciprocating parts within the cabin of the locomotive and makes the balancing easy. For low-speed locomotives, especially goods engines, with a large pull on the draw-bar and comparatively little horse-power, the gearing is of decided advantage in many respects and is likely to be commonly adopted. The locomotive built by the A.E.G. for the B.L.S. is of a design novel in electric traction on Swiss railways. It has the motors placed high in the cabin, and cranks on the motor shafts, from which motion is transmitted to the horizontal connecting rods of the driving wheel axles, by means of a system of intermediate connecting rods that reciprocate up and down. The geared and the gearless type of locomotives will probably have each a more or less distinctly defined field of application of their own, though there is a field accessible to

* Abstract of a Paper read at the Meeting of the Institution of Mechanical Engineers at Zurich.

both types, where the one as well as the other represent more or less a compromise. Practical experience alone can determine which type will be the more advantageous to adopt in each individual case. The question of gears is more or less a question of electric traction motors proper and cannot be discussed except by going into the very details of their design, nor without considering certain particular features of the different systems of motors and their adaptability to high or low speeds. It need only be said here that, in general, with low speed, and more particularly with powerful low-speed locomotives, the adoption of gears permits of a more satisfactory design, construction and operation, while, with all high-speed locomotives, the elimination of gears is advantageous. The locomotives of the B.L.S. are neither high or low speed. Their maximum power is, however, developed on up gradients at decidedly low speeds, while higher speeds occur on the down slopes with no load, and on the gentle slopes or levels when the motors are not fully loaded. It will be highly interesting and important to compare the two radically different types of locomotives on the B.L.S., where there are reasons for the existence of each.

The transformers on the locomotives were arranged to permit of working at half contact line voltage, if, for one reason or another, 15,000 should have proved impracticable. In fact, at the time when all trains were steam-driven and the electric vehicles were being run for experimental purposes, some flashing over from smoky insulators in the Hondrich tunnel, just beyond Spiez, was observed, and a periodical cleaning of the insulators was carried out. Since steam traction has been discontinued, no such trouble has been experienced, and it is expected, as the smoke nuisance will not exist on the new line, that the voltage will not require reduction.

This Paper would be incomplete if it did not consider, in addition to the electric railways working or building, the work, more scientific than practical, done for years in Switzerland, with a view to elucidating the general railway electrification question under Swiss conditions, to determining by investigation the merits of the several systems and the cost of plant and of operation; and to making a fair comparison between steam and electricity for definite lines or groups of lines. Work of this kind has been and is still being done by a society with the title Schweizerische Studiencommission für electrischen Bahnbetrieb. It was founded on the initiative of Dr. E. Tissot, and under the auspices of the Society of the Electricians of Switzerland. It was constituted and commenced work in 1904, and railways, electricity works, manufacturing firms and scientific men are represented.

To-day it is easy to state the principal conclusions of the Studiencommission as to systems of electric traction, and more particularly as to the standardised frequency of the alternating current used for electric traction on the railways mentioned in this Paper. These conclusions are exhibited in their essence and in practice in the series of railways described, beginning with the Seebach-Wettingen experimental line and ending with the Engadine line of the Rhätische Bahn now in course of construction.

It is, of course, difficult to estimate the value and influence of the Studiencommission. It is, however, certain that the collaboration in the Commission of representatives of interests in competition with each other in business has acted beneficially so as to make the question of system less one of competition and more one of general scientific and common practical interest.

After having arrived at the conclusions set forth the Studiencommission made different comparative projects with special reference to the St. Gothard Railway as a railway, which, before all others in Switzerland, appeared to be ready for electrification. For more than a hundred kilometres it goes through country with tens of thousands of hydraulic horse-power doing nothing but embellishing the landscape, while the locomotives with their smoke detract from its beauty. The traffic on the St. Gothard line has developed to the limits of steam operation. There is a continuous and permanent demand for more powerful engines for dealing on the long and heavy gradients with a tonnage comparable with that of the busiest flat country main-line railways. The railway, with a length of 274 km. (170⅛ miles), presents the problem of electrification in a still more general way than does the Lötschberg, firstly because there the creation of the power stations forms part of the problem, and secondly because the more or less level sections north and south of the steep slopes require high speeds.

The Studiencommission has, in addition to certain alternative suggestions, prepared two complete projects with great care and attention, as if they were tendering for a contract. The first project, called "1904," has been prepared for the sole purpose of a fair and complete comparison of actual steam traction with hypothetical electric traction under known precise conditions of traffic. The second project, called "Future," pre-supposes a traffic considerably in excess of the traffic of 1907, which holds the record up to now, at the same time adopting speeds and accelerations more or less in excess of those accepted for the hypothetical electric traction of "1904."

The author thinks it sufficient to make a few indications, some of which have been published by the Schweizerische Studiencommission,* to give an idea of what would have been required in 1904 and what is expected in the "future" for electric traction on the St. Gothard Railway. Of the figures that follow, those in parentheses refer to the "future." The speeds of express trains are from 85 (90) km. per hour on the level to 40 (50) on 1 in 40 gradient. The speeds of passenger trains are 55 (75) to 26 (50), and those of freight trains 38 (45) to 18 (35) km. per hour.

Section of the Federal Railways. — No individual figures on hand. — Experiments in 1906 and 1907. Regular operation from 1 Dec., 1907, until May, 1909. — Figures not on hand. — Statistical figures not on hand. — In course of construction. — In course of construction. — In course of construction.

* Maximum weight of passenger trains 30t., of freight trains 400-600 tons without locomotive. ‡ 60-200 tons without locomotive. § Excluding Brunig but including St. Gothard.
† From June 1, 1908, until May 31, 1909; 22,933,000 ton-km. without and 32,458,000 with locomotive weight. ‖ Excluding St. Gothard and Brunig.

The starting horse-power is limited to 1·25 times the normal horse-power on 1 in 40 gradients; acceleration as such is, however, limited to 0·15 (0·20) m/s/s with expresses, to 0·15 (0·30) m/s/s with passenger and to 0·10 (0·10) m/s/s with goods trains. The weights of the trains will not increase much in future; they were, in 1904, with express trains on most sections 200-220 (280-350 maximum) tons, with passenger trains 120-180 (240-350 maximum), with goods trains on the main line 350-380 (500 maximum), and on other sections 270-350 (330-370 maximum) tons, all exclusive of locomotives. In fact, goods trains being moved by two eight-wheelers at the head and one at the rear are a usual sight on the slopes. There will be required about 19 (21) motor cars of 200-500 (400-1,100) H.P., about 9 (15) fast locomotives of 1,800 (2,200) H.P., and about 37 (38) goods locomotives of 800 (1,500) H.P.

Single-phase alternating current is adopted of a frequency of 15 and of a voltage of 15,000 for the supply to sections immediately adjacent, and of perhaps three times the pressure for transmission to transformer sub-stations supplying the sections remote from the power station. There will be two (three) power stations required, the most important one situated a little below Airolo, near the Ambri-Piotta station, having the Lake Ritom, into which other lakes drain, as an enormous water-power storage basin. The power required for traction is considerable and the load line has enormous peaks. The total power developed on the tread of the locomotive vehicles on the whole line will amount to about 14,000 (22,000) H.P. maximum and about 5,000 (10,000) H.P., on the average. On individual sections the proportion of maximum to average is, however, less favourable. There will be required from the hydraulic turbines 27,000 (46,000) H.P. maximum. There will be installed in two (three) power stations hydro-electric machinery of about 50,000 (95,000) H.P., including stand-bys. It is expected under "future" conditions to tap eventually about 26,000,000 m.³ of water from the Lake Ritom, temporarily of course, leaving but 6,000,000 m.³ in it, and thus lowering its surface more than 30 m. (100 ft.) a procedure which is of no material inconvenience in the case of a mountain lake with precipitous shores. In the case of the St. Gothard, the Studien-commission has considered the employment of accumulator batteries for storing power locally, independently of the site of the water power stations, and for providing for the local peak loads. These have, however, been found uneconomical, on account of the greatly increased expenditure for sub-station machinery, plant, maintenance and operation. Water storage was resorted to exclusively for providing for peak loads, because it was indispensable in allowing

Digitized by Google

for the seasonal variations of fresh water supply in relation to the seasonal variations of traffic. While the storage for the latter purposes requires large reservoirs, storage for the former purposes requires reservoirs comparatively small. In the case of the St. Gothard the power station at Ambri-Piotta, with the Lake Ritom and its 36,000,000. m.³ on a level more than 800 metres above, as a storage basin will provide for the seasonal variations and other large variations not of a simple peak character, while small basins near the other (others) power station (power stations) will deal with the peak loads in their particular district of supply.

The total cost of the new plant, new rolling stock and accessories, alterations on telegraphs, telephones and signals, supervision, interest during construction, will amount to about 44 (67) million francs. These figures give an idea of the magnitude of this electrification which is expected to be started before long. The Federal Railways, a few years ago, acquired ample water powers in five places along the line.

In conclusion, railway electrification has made, and is making, noteworthy rather than rapid progress in Switzerland. As regards system, single-phase current of low frequency (15) and high-line voltage, varying from 5,000 to 15,000 according to circumstances, is being sanctioned by experience and by authority. An important electrification of a new line, the Lötschberg, is about to be carried out in the immediate future, and a still more important one, that of the St. Gothard Railway, is well prepared for by the investigations of the Schweizerische Studiencommission für electrischen Bahnbetrieb and by the Federal Railways' purchase of water powers along the line. Railway electrification and electric traction on a large scale is in a great measure a problem of power station economics. The heavy variations of load, and those due to rapid seasonal variations in the fresh-water supply, make, under Swiss conditions, water storage desirable and even imperative. All electrification in Switzerland is directly connected with the utilisation of water power.

STEAM TURBINES.*

BY H. ZOELLY
(of Zurich).

Summary.—The author gives an historical account of the progress in theory and practice made in the design of the type of steam turbine that bears his name. He also shows how certain details must be modified in accordance with the work the turbine is likely to be called upon to do.

Based chiefly upon his experience gained with water turbines, the author commenced about 15 years ago to experiment with steam turbines, considering that the steam turbine would resemble in most respects the water turbine, only using a much higher working pressure. For this reason he was guided in adopting the pure action or impulse type of steam turbine. As is almost invariably the case when experimenting with any new kind of machinery, it is very difficult to combine satisfactorily the ideas of the theoretical mind with those of the practical. In order to attain the most favourable efficiency, a very high circumferential speed of the rotor is necessary; but to obtain this result within economical limits is the chief difficulty of the constructor, whose contention was that a heavy and solid design was absolutely necessary for safe working as well as being a cheaper form to construct.

The first machine was designed on the radial-flow principle. In its design too much regard was paid to practical constructive considerations and too little to theory. The second machine was constructed on the same principle; the blades, however, were curved in preference to the previously flat ones, the steam in this case impinging against the rotor blades in a radial direction. This form of construction constituted quite a considerable improvement upon the earlier design. Already at this period it was found advisable to divide the drops in pressure into at least six and sometimes 10 to 12 separate pressure stages. The diameters of the rotor wheels were also increased towards the exhaust end in order to cope better with the increased volume of the steam.

As already observed, the principle of the action (impulse) type has been recognised and adopted from the commencement as being the best; the only alterations that took place for some time were in the manner of guiding the steam on to the wheels. The first wheels were constructed after the manner of the Pelton wheel, against which the steam impinged tangentially, after being directed through separate guide channels. It soon became apparent, however, that after impact, the steam became too dispersed. It was then decided to expand the steam axially instead of radially, at first only in the low-pressure stages, but subsequently, throughout the whole turbine. This method had formerly been adopted by English constructors as being the most practical.

What has always been, and is still, the most characteristic feature of the Zoelly turbine, is the designing of the runner wheels and guide channels in the diaphragms; the former of which, in spite of the high factor of safety that is necessary, are enabled to be given a relatively high circumferential velocity. Consequently greater latitude is permissible in regard to the number of pressure stages, and the speed of the steam in each. From the beginning two very characteristic diagrams were prepared (Figs. 1 and 2). These diagrams were obtained from theoretical calculations, which have since been proved by actual results. Fig. 1 contains as abscissæ the pressure relation per stage $p1/p2$ (where $p1$ = the initial steam pressure in atmospheres absolute, and $p2$ = the final steam pressure in atmospheres absolute in the same stage), and as ordinates the requisite number of stages for steam expanding from 10 atmospheres to 0·1 atmosphere (that is, 142 lb. per square inch to 1·42 lb. per square inch), assuming that the pressure ratio $p1/p2$ of the steam both before and after passing through the guide channels is constant. Fig. 2 shows the steam velocity resulting from pressure ratios given for various initial pressures. For a ratio pressure fall of $p1/p2 = 1{\cdot}732$, it follows from Fig. 1 that about nine stages are required. For relative pressure falls, where $p1/p2 = 1{\cdot}1, 1{\cdot}2, 1{\cdot}3, 2{\cdot}1, 3, 4{\cdot}6$, the requisite and corresponding

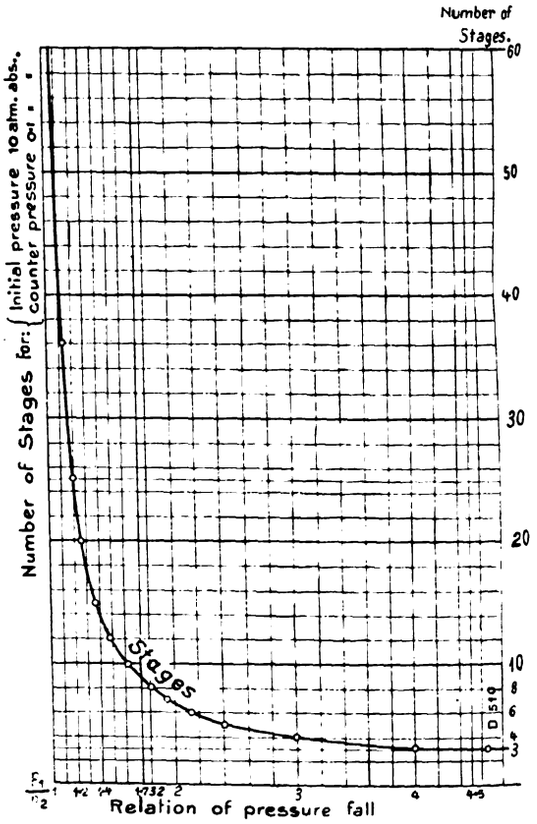

FIG. 1.—CURVE SHOWING NUMBER OF STAGES REQUIRED FOR EXPANDING FROM 10 ATM. TO VARIOUS FINAL PRESSURES.

number of stages for a total expansion of from 10 to 0·1 atmospheres absolute would be 42, 25, 18, 6, 4 and 3 respectively. Should we assume a greater ratio of pressure fall than 1·732 for the purpose of saving stages, then, in order to have only four stages, it is necessary to have a ratio pressure fall of $p1/p2 = 3$.

From Fig. 2, for a mean initial pressure of $p1 = 4$ atmospheres absolute, the steam velocity would be equal to 577 metres (1,893 ft.) per second. This steam velocity, on the other hand, would require a circumferential speed of about 250 metres (820 ft.) per second (for a simple velocity wheel) in order to obtain a reasonable efficiency. Again, if we take a smaller ratio of pressure fall than 1·732 1, for instance 1·30/1, the necessary number of stages would be increased from 9 to 18, that is, exactly double. Such a turbine would be far too complicated and expensive; besides it would not then work with perfect economy owing to the greater friction of the runner wheels and the greater length of steam passage.

After carefully weighing up all these considerations, the ratio pressure fall of $p1/p2 = 1{\cdot}73$ was chosen, as representing the best combination of efficiency and practical constructional economy. This pressure fall is called the "critical fall," and when this is exceeded then the resulting steam velocity approaches the velocity of sound.

* Abstract of a Paper read at the meeting of the Institution of Mechanical Engineers at Zürich.

Digitized by Google

Directly one wishes to utilise a substantially higher pressure fall per stage, then it becomes necessary to depart from the simple construction of parallel guide nozzles which is peculiar to the Zoelly turbine, so that, instead of the simple parallel nozzle, one must adopt the expanding or "Laval" type of nozzle. The reason that Parsons employs such a small pressure fall per stage is entirely to keep as low as possible the losses through leakage which are unavoidable in reaction turbines.

The author does not intend to deal more fully with the various stages of improvement, which from that period have been solely of a constructional character, but will describe the Zoelly turbine as manufactured at the present time by Messrs. Escher, Wyss & Co. For turbines of 3,000 revs. per min. eight stages are usually employed; for 1,500 revs. per min., 12 stages; and for 1,000 revs. per min., 16 stages. The first diaphragm plate (guide wheel) of the high-speed turbines has nozzles which extend for a portion of the circumference only in the bottom half of the diaphragms; whilst in the other diaphragms, the nozzles usually extend completely round the circumference. In the case of large units, however, steam is admitted through channels extending completely round the circumference for all stages.

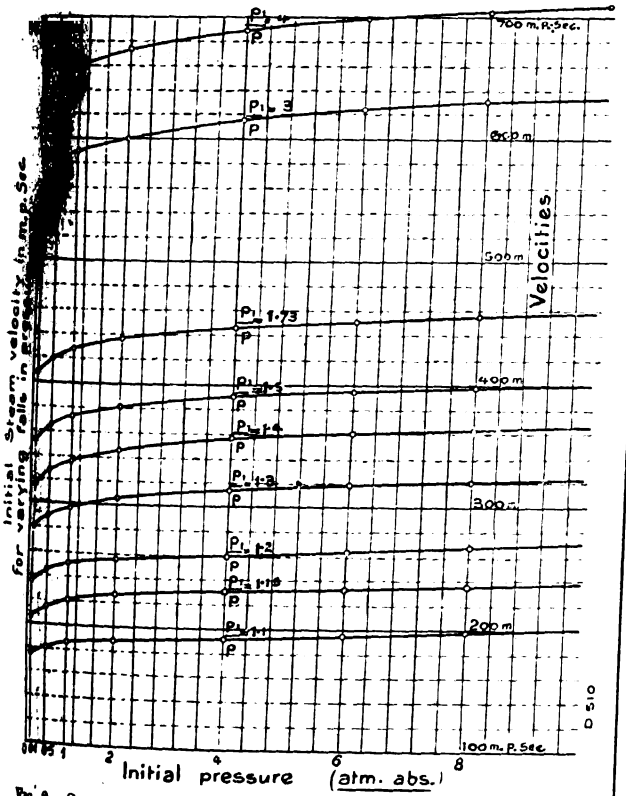

FIG. 2.—CURVE SHOWING STEAM VELOCITIES FOR VARYING INITIAL PRESSURES.

The governing is effected simply by throttling the live steam and not by varying the number of channels through which the steam is admitted. The throttle valve is actuated by oil under pressure in a small cylinder (servo motor) by hydraulic action, the oil being supplied by a small pump directly driven from the shaft. This is the same form of governing as that which has been found to work so successfully for water turbines, and is now being universally adopted by nearly all the different makers of steam turbines on the Continent. Its inherent advantages are that it is extremely simple and reliable, and, contrary to fears expressed by some engineers, this method of governing works particularly economically at partial loads, as is seen from the results shown later. This, however, is only possible when simple velocity wheels are used in connection with parallel guide nozzles throughout the whole turbine, and provided that the most favourable choice is made in regard to the subdivision of stages. The conclusion arrived at is that the compound velocity wheel design is only advisable in special cases, as, for instance, in shipbuilding, where a lower propeller speed is absolutely necessary.

The chief reasons against the adoption of the compound wheel design in the case of stationary turbines are the lower steam efficiency and the necessity of a complicated governing apparatus, in order to obtain a favourable consumption at partial loads. In this type of turbine the governing has to be carried out by controlling the number of nozzles through which the steam enters. Experience has shown that this method does not satisfactorily answer practical requirements—*i.e.*, continuous safe running. Besides, the governing is not so accurate and is less suitable for running in parallel with other machines.

The author would especially like to mention that for many years he has experimented with turbines designed with a high steam velocity and compound wheels. The many series of tests which he has carried out at different periods have all gone to show that under the most favourable conditions it is not possible to obtain a higher thermal efficiency with compound velocity wheels than 58 per cent., whereas with a turbine designed with entirely simple velocity stages it is possible to obtain an efficiency of 73 per cent. and more. If, therefore, in an impulse turbine it is found necessary to employ a combination design of compound and single velocity stages for such special cases as exceptionally large units for land purposes, or where it is necessary to work at low revolutions, the comparatively poor efficiency of the high-pressure compound velocity stage or stages must be compensated for as well as is possible by obtaining a relatively higher efficiency in the subsequent low-pressure single-velocity stages. For this purpose almost as many pressure stages must, on the whole, be provided for as in a design employing only single velocity stages.

It is often objected to in the Zoelly turbines that too high a pressure and temperature exist in the first pressure stage; against this it must be said that even with Zoelly turbines likewise large pressure falls can be utilised for the first stage even within comparatively economical limits, provided that the lower pressure or subsequent stages have a correspondingly lower pressure fall and thus consequently work with a higher efficiency. In this way it happens that by the application of live steam at about 170 lb. per square inch and 570°F. (300°C.) the pressure and temperature of steam after expansion in the first stage is 70 lb. per square inch and 465°F. (240°C.). Such conditions, as regards the solidity and durability of the casing and its stuffing boxes are nowadays easily mastered by steam turbine builders.

ELECTRICAL RESISTANCE OF PURE METALS—ESPECIALLY MERCURY—AT LIQUID HELIUM TEMPERATURES.*

BY H. KAMERLINGH ONNES.

In continuation of the author's work on liquid helium temperatures, he now indicates that liquid helium has been successfully transferred from the apparatus in which it was liquefied to a helium cryostat connected with the former. It has also been found that liquid helium is an excellent insulator—a fact which had not been definitely established previous to this. This behaviour of liquid helium is of considerable importance, since the resistance measurements were made with bare wires.

The experiments were concerned mainly with the resistance of gold and of mercury at helium temperatures. As regards the former metal, the resistance of pure gold is already inappreciable at the boiling point of liquid helium as was confirmed by determining the resistance of a gold wire in liquid helium and then estimating the resistance by extrapolation on the analogy of the platinum measurements. Within the limits of experimental error, which are, however, greater for this experiment than was the case for the others, the estimated resistance is supported by the direct measurement. The conclusion that the resistance of pure gold vanishes at helium temperatures is hereby greatly strengthened.

In the case of mercury, a formula has previously been deduced by the author for the resistance of solid mercury, this formula being based upon the idea of resistance vibrators. From this it was concluded: (1) That the resistance of pure mercury would be found to be much smaller at the boiling point of helium than at hydrogen temperatures, although its accurate quantitative determination would still be obtainable by experiment; (2) that the resistance at that stage would not yet be independent of the temperature; and (3) that at very low temperatures, such as could be obtained by helium evaporating under reduced pressure, the resistance would, within the limits of experimental accuracy, become zero.

The experiments have completely confirmed this forecast. While the resistance at 13·9°K. (13·9° on the Krypton thermometer) is still 0·034 times the resistance of solid mercury extrapolated to 0°C., at 4·3°K. it is only 0·0013, while at 3°K. it falls to less than 0·0001.

* From the "Proceedings" of the Koninklijke Akademie van Wetenschappen, Amsterdam. Slightly abbreviated.

Digitized by Google

The results just given were founded on a single experiment and were, therefore, communicated with all reserve.

The author has now, in a later communication, made a more accurate experimental examination of the resistance of pure mercury at liquid helium temperatures. The measurements were made with the differential galvanometer by the method of overlapping shunts (Kohlrausch) and also by the method of the measurement of current strength and of potential difference. By this it is confirmed that at 3°K. the value of the resistance sinks to below 0·0001 times the value of the resistance of solid mercury at 0°C. extrapolated from the melting point. But from the present measurements it has also been ascertained that the actual value of the resistance is very much smaller than this upper limit which was ascribed to it from former measurements.

The value of the mercury resistance used was 172·7 ohms. in the liquid condition at 0°C.; extrapolation from the melting point to 0°C. by means of the temperature coefficient of solid mercury gives a resistance corresponding to this of 39·7 ohms. in the solid state. At 4·3°K. this had sunk to 0·084 ohm., that is, 0·0021 times the resistance which the solid mercury would have at 0°C. At 3°K. the resistance was found to have fallen below 3×10^{-6} ohm, that is to one-ten-millionth of the value which it would have at 0°C. As the temperature sank further to 1·5°K, this value remained the upper limit of the resistance.

The next step was to look for the point at which the resistance first becomes measurable as the temperature is raised. The temperature of this point was found to be slightly more than 4·2°K. at which the resistance was found to be 230 microhms or one-hundred-thousandth of the resistance (solid) at 0°C.

The more the upper limit which can be ascribed to the resistance remaining at helium temperatures decreases, the more important becomes the observed phenomenon that the resistance becomes practically zero. When the specific resistance of a circuit becomes a million times smaller than that of the best conductors at ordinary temperatures it will, in the majority of cases, be just as if electrical resistance no longer existed under those conditions. If conductors could be obtained which could be regarded as being devoid of resistance so long as their cross-section was not excessively small, or conductors of the smallest possible sections, either cylindrical with dimensions of the order of the wave length of light, or films of molecular dimensions, whose resistance would be small; if the Joulean development of heat had no longer to be reckoned with when increasing the current in a bobbin to exceedingly high values, because the development of heat in a constant-current circuit could be made extremely small compared with the latent heat of vaporisation of the liquid which can be used for cooling,—these further experiments in all possible directions would give the fullest promise, notwithstanding the great difficulties which are encountered when working with liquid helium. It is therefore all the more necessary to establish beyond all possibility of doubt the property of which advantage would be taken in such experiments. With this end in view modified measurements are being made.

THE ELECTRICAL EQUIPMENT OF THE S.S. "OLYMPIC" AND "TITANIC."

(*Concluded from page 619.*)

Summary.—In this article are described the various uses to which electricity is put on board the two latest White Star liners, the "Olympic" and "Titanic." These include, besides lighting, power for winches, cranes, fans, water-tight doors and stoking and helm indicators. The cooking and heating equipment are also electrically worked, while a complete telephone and wireless installation is to be found on board. The differences between marine and land practice are noted.

Winches and Cranes.

One of the little discomforts sometimes associated with modern ocean travelling is the noise caused by winches and other deck appliances, and although when on the high seas these are not much in evidence, yet when approaching port it is sometimes necessary to use them, as for instance when handling mails or passengers' luggage preparatory to disembarkation. With a view to avoiding this on the "Olympic" the aid of electricity has again been invoked, with the result that all the winches in the vicinity of the passenger accommodation, and the cargo cranes are electrically driven. The latter (*see* Fig. 12) have been made by Messrs. Stothert & Pitt, six having a capacity of 50 cwt. each, and two of 30 cwt. each. These cranes are fitted at the three after hatches and at the forward hatch near the passenger quarters.

The 50-cwt. cranes have radii from 26 ft. to 29 ft. and the 30-cwt. crane a radius of 26 ft. 6 in. The height of lift is about 100 ft. for the larger cranes and 80 ft. for the smaller. The lifting gear is fitted with the "free barrel" system with interlocks, which contributes so much to the smooth and e working necessary for cranes on a first-class passenger boa

The cranes are operated by separate motors for lifting slewing; the 50-cwt. cranes have 40 H.P. motors for the lift 5 H.P. for the slew, whilst the 30-cwt. cranes have 30 H.P. mo for the lift and 3 H.P. for the slew. The larger cranes lift 160 ft. per min, and the smaller at 200 ft. per min., the sle speed being about 500 ft. per min. in each case. The bra

Fig. 9.—Stoking Indicator.

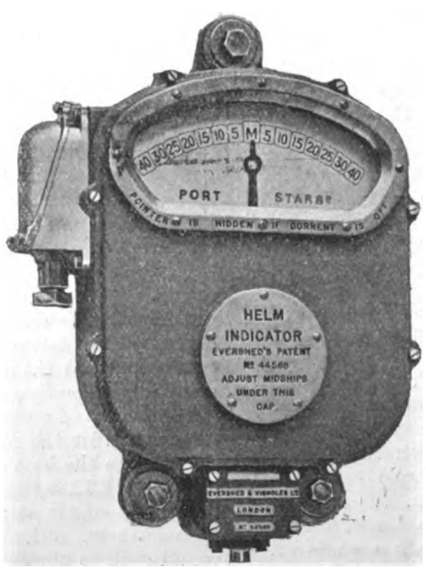

Fig. 10.—Helm Indicator.

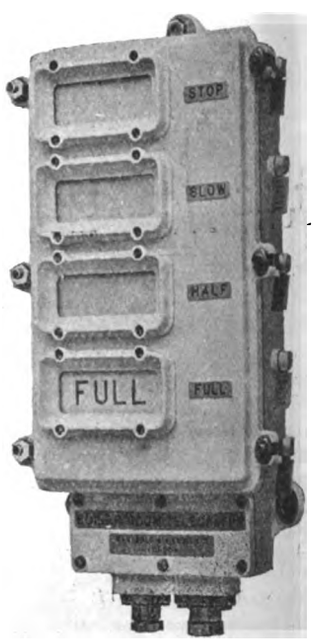

Fig. 11.—Boiler Room Orders Telegra

Digitized by Google

both of the slewing and lifting gear are interlocked with the controller, so that current cannot be given to the motors when the brake is hard down.

In addition to the electric cranes, there are four 3-ton electric cargo winches at the hatches, as well as four 15-cwt. electric boat winches made by the Sunderland Forge and Engineering Co. (Ltd.) A 3-ton cargo winch is shown in Fig. 13.

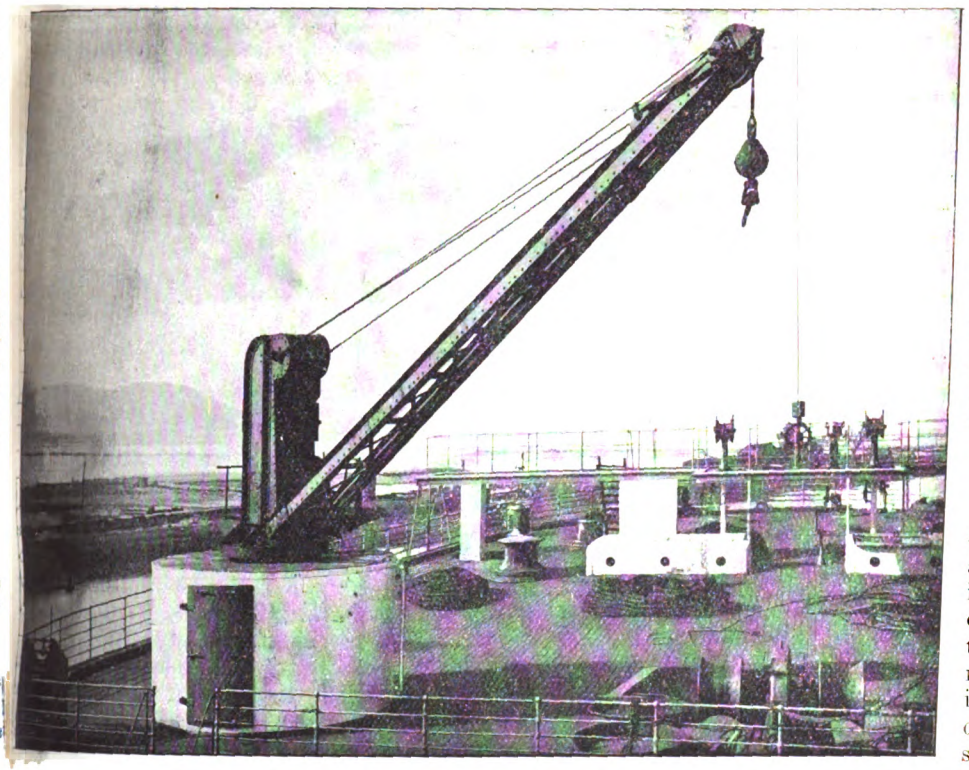

FIG. 12.—2½-TON ELECTRIC CRANE.

ACCESSORY POWER GEAR.

In all there are 150 motors on board varying from ½ to 40 H.P., to which it is impossible here to refer in detail. Special mention may, however, be made of several novelties; for instance, there are Kiiroy stoking indicators which automatically transmit orders from the engine room to each stokehold for the firing of each of the furnaces at correct and predetermined intervals of time, thus ensuring good combustion with resultant economy. There are also illuminated telegraphs in each boiler room which enable the engineer on watch in the engine room to communicate his orders to each stokehold; in addition to which he can speak to those in charge there by means of a loud-speaking telephone and thus be in communication even when all the water-tight doors are closed, and each compartment therefore isolated, as would obtain in thick weather. The convenience and additional security gained by this may be gauged when it is considered that there are no fewer than six boiler rooms and 11 stokeholds, the forward one being no less than 320 ft. from the engine room. Evershed helm indicators, for so many years used in the Navy, have been supplied and indicate on the bridge the position of the rudder. All these signalling devices have been manufactured by Messrs. Evershed & Vignoles in accordance with the builders' specified requirements. Some of these devices are shown in Figs. 9 to 11.

The steam whistles, previously referred to, are also electrically controlled, the officer on the bridge having merely to close a switch to give the blast, whilst there is also an electric time control arrangement whereby the whistle is automatically blowing for 8 to 10 seconds every minute without further attention during thick weather, the mechanism being Mr. W. J. Willett Bruce's patent.

The watertight doors are also electrically controlled from the captain's bridge, the arrangement being such that by merely closing a switch all the doors can be simultaneously shut, a bell having previously been rung to give warning below decks.

CLOCKS.

The clocks, of which there are 48 throughout the vessel, are all actuated electrically, and worked in complete synchronism, so that each registers exactly the same time; they are controlled by a master clock (*see* Fig. 14) placed in the chart room under the control of the officers, who can set them backwards and forwards according to the longitude.

The equipment, like that on many large liners of recent years, has been supplied by the Magneta Time Co. Ltd., and consists of the same type of Magneta apparatus that is installed in the chief postal buildings of London, with the modifications necessary for ship conditions, the balance escapement of the master clock being of a similar class to that used on marine chronometers. The master clock is capable of running 100 secondary clocks. Specially designed junction boxes have been fixed throughout the vessel, so that extra dials can be added

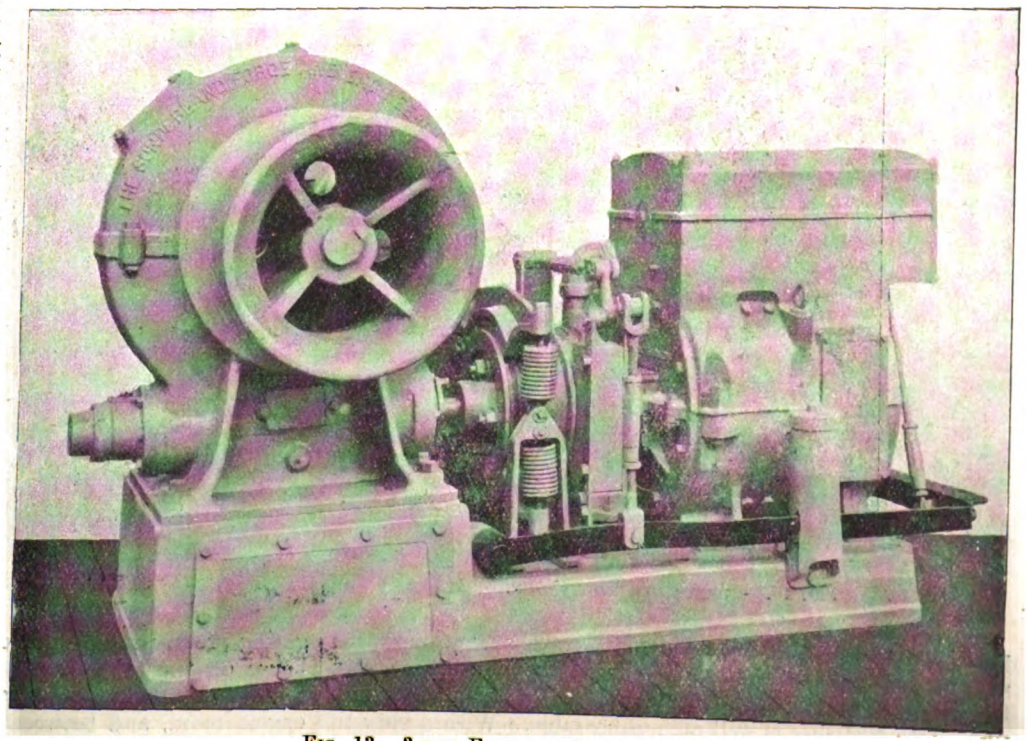

FIG. 13.—3-TON ELECTRIC CARGO WINCH.

Digitized by Google

at any time without disturbing the existing wiring. As in all Magneta installations, batteries and contact points are abolished, and no outside source of current is resorted to; there is, therefore, nothing to maintain or renew.

Heating.

The heating of the ship is effected in several ways, partly in conjunction with the ventilation system, which latter is

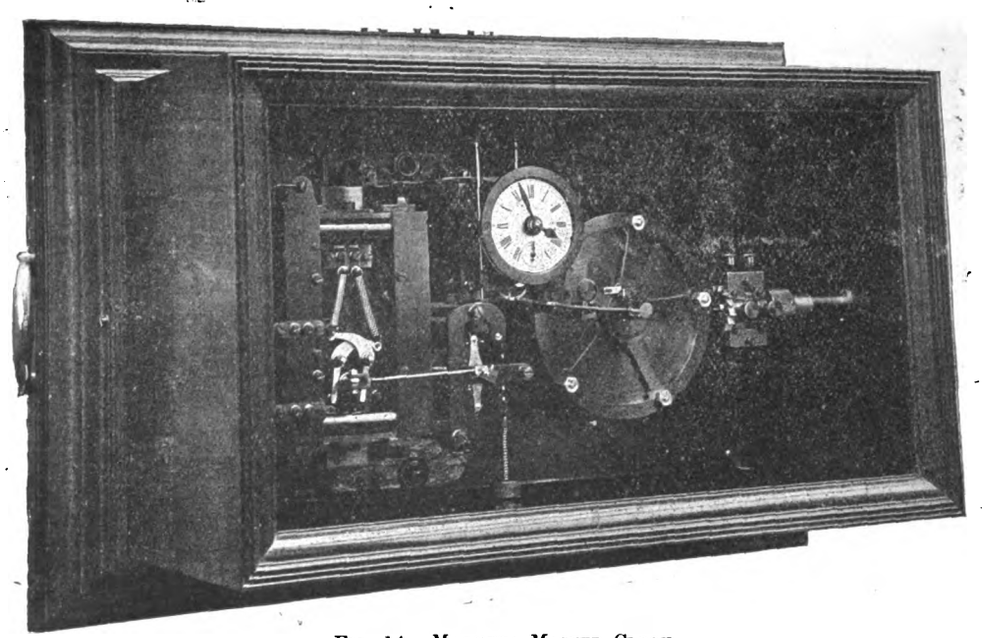

Fig. 14.—Magneta Master Clock.

installed in an elaborate and probably more perfect way than any yet attempted on board ship. Broadly speaking, the principle adopted is that in the large third-class compartments hot air is driven by means of the fans above referred to through insulated trunks in all directions, thus maintaining a pleasant temperature even in the coldest weather at the extremities of the vessel. The ventilation and heating of the first-class accommodation, on the other hand, involves some special

Fig. 15.—Forecastle Telephone.

problems, as the passengers' demands are so various; for instance, an American travelling from the Southern States frequently requires and is accustomed to an amount of heat which to a Britisher is well-nigh unbearable. With a view to meeting all requirements it was decided, after careful thought, to provide the first-class accommodation with ventilation both in the passages and individual state rooms—the latter under the control of the passengers—by means of air which is warmed to a moderate degree so as to maintain an even and pleasant temperature. This may be regarded as a warm-air system only, as distinct from a hot-air one, on the "Plenum" method. Each first-class room is in addition fitted with an electric heater of ample capacity, so that passengers requiring additional warmth can obtain it to the desired extent, whilst those who prefer the cooler atmosphere are equally catered for. In addition to the hot and warm air delivery fans referred to there are a large number of "suction" fans drawing the foul air from the lavatories, galleys, pantries, and other quarters, so that not merely is fresh air brought into the ship but all vitiated air is removed through that portion of the accommodation which, unless ventilated, might in itself prove objectionable. The mechanical system of ventilation adopted incidentally renders superfluous the imposing array of cowls so noticeable on the decks of many liners, ventilator cowls being on the "Olympic" and "Titanic," to use an Irishism, conspicuous by their absence. There are no fewer than 520 Prometheus electric heaters installed throughout the vessel, taking a collective current of over 5,000 amps.

Needless to say, the gymnastic appliances are also electrically driven, and include riding and rotating machines and other apparatus for physical drill. There are also electric Turkish baths.

Telephones.

The telephone installation is divided into two sections, viz., the navigating group and the internal system. The navi-

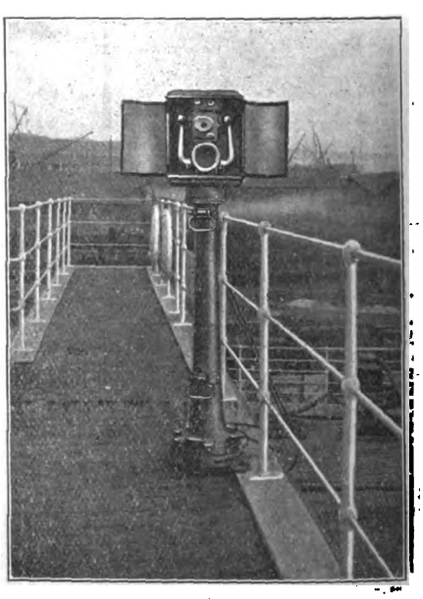

Fig 16.—Poop Instrument.

gating group provides for communication between the wheelhouse on the bridge and the forecastle, crow's nest, engine room, and poop; also between the chief engineer's cabin and engine room, and between the engine room and the various stokeholds.

The instruments employed are Messrs. Alfred Graham & Co.'s loud-speaking Navy telephones of the latest type. Exc

Digitized by Google

in the chief engineer's room, where the cabin type is fitted, the telephones are of the "Universal" pattern, in which calls are given by means of an interrupter or bell as well as by voice. The apparatus is mounted in special forms to suit the various positions.

At the forecastle and poop (Figs. 15 and 16) the instruments are contained within a polished brass casing mounted on a pillar, and the whole fitting is arranged in portable form, so that the apparatus can be used at two alternative positions in the case of the forecastle set and a second position at the poop. For the crow's nest, the telephone is mounted within a metal hood, and this set also is portable.

In the wheel house on the bridge (Fig. 17) four instruments are fitted, and each telephone is provided with an indicating device, and in addition to a flag showing, as is usual, a signal lamp is caused to glow upon a call being received.

In the engine room (Fig. 18) three telephones are employed, and the instrument for communicating with the boiler rooms operates in conjunction with a combined switch and indicator giving both lamp and flag signals as previously referred to. In each boiler room, the telephone is mounted within a metal hood, and in addition a special calling receiver is provided at each station as well as a visual indicator.

The current for operating the system is obtained from the ship's lighting circuit, the pressure being reduced for telephonic working by means of resistances, and the noise of commutation, inherent in machine generated supply, is eliminated by the introduction of inductance coils. A standby battery is also provided, and is introduced in the circuit, should the main supply fail, by means of an automatic switch.

The internal system provides for inter-communication between a number of cabins through a central exchange, which has a capacity of 50 lines.

The switchboard is arranged to give a lamp signal upon a call being made, and in addition to the usual audible signal, a voice call can be given to the exchange from any station in connection, so that the rapidity of operation is assured.

The user in one of the cabins has simply to pick up the telephone and say straightaway the station he wishes to speak to and a loud receiver at the exchange gives the instruction, and the operator seeing a lamp glowing corresponding with the calling station then connects the calling station with the station required, thus obviating the usual delay in communicating with the calling station and ascertaining the position required.

The current supply is obtained from the lighting circuit, as in the case of the navigating telephone system, and the automatic switch and standby battery is contained within the exchange switchboard casing.

The telephone sets in each cabin are of Graham's intermediate loud-speaking type, and comprise a hand set with a circular metal push and terminal box. At the majority of

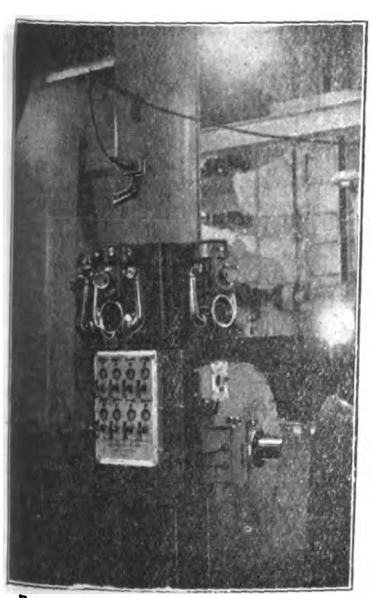

Fig 18.—Engine Room Telephones.

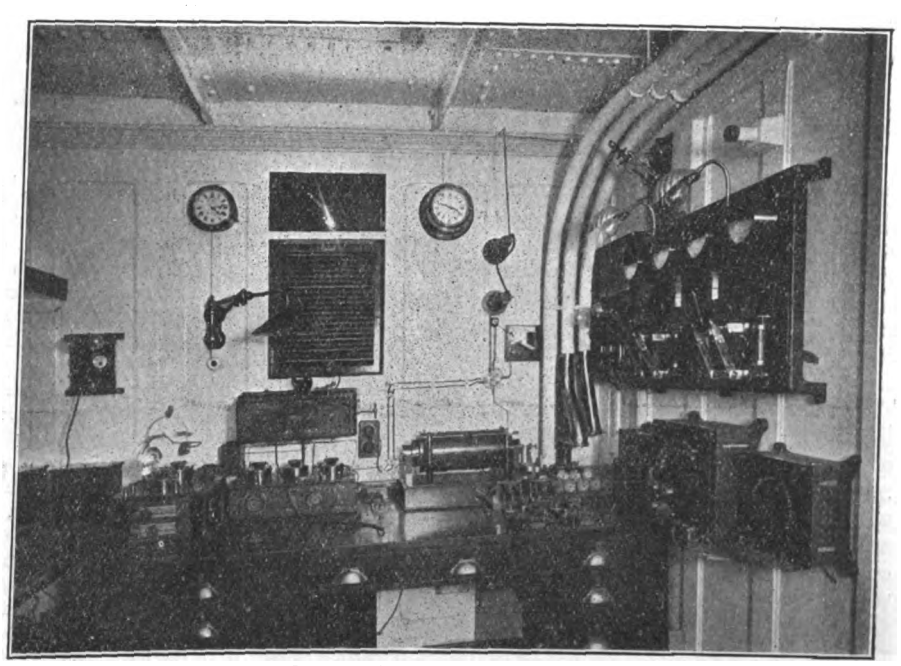

Fig. 20.—Marconi Apparatus in Operating Cabin.

Digitized by Google

the positions the fittings are silver plated, and at others of polished and lacquered brass. Junction boxes have been introduced so as to facilitate testing and extension of the installation.

In addition to the exchange system, a separate group of circuits is provided for direct communication between the various pantries and the galley, baker's shop, butcher's shop, &c.

In foggy weather, when approaching land or in the vicinity of a lightship, submarine bells are sounded, attached thereto, under the sea, and the signals are heard by a telephone in the chart room, enabling those in charge of the vessel, to tell its precise position, whilst wireless telegraphy embodying Marconi's latest inventions for long-distance transmission gives additional security, and provides facilities for communication between ship and ship, and ship and shore, which are now too well recognised to need further description.

"Wireless" Equipment.

No modern liner is complete without a wireless telegraph installation. With such an equipment not only is communication with ship or shore possible in case of accidents, but the passenger is enabled during the voyage to keep himself in touch with the world's news. The "wireless" apparatus on the "Olympic" is of the Marconi type and consists of a 5 kw. motor-generator set combined with the latest type of valve receiver installed as a standby. The installation is designed to provide, when employed with a suitable aerial having a mean height of 170 ft., a working range of 250 nautical miles over water, and a maximum range considerably exceeding the above figure. It is arranged to tune when transmitting to waves of 300 and 600 metres, and to tune when receiving to all waves between 100 and 2,500 metres. Two masts, 200 ft. high, placed 600 ft. apart, are used for the support of the aerial, which is of the twin T type, one aerial only of appropriate type being employed for the double purpose of transmitting and receiving. The earth connection is made by insulated cable to convenient points on the hull of the vessel.

Continuous current at 110 volts is supplied to a continuous-current motor which is mounted on a common bed with and direct-coupled to an alternating-current generator. The latter has an output of 5 kw. at 300 volts. The manipulating gear consists of a Morse key which actuates electrically an electromagnetic relay key in the transformer primary circuit. The Morse key is provided with telephone short-circuiting contacts to prevent the operator's ear becoming insensitive owing to the noise in the telephone during transmission. The receiver is a standard magnetic detector and multiple tuner, by which all waves between 100 and 2,500 metres wave length can be received. The multiple tuner is calibrated to permit of the instrument being set to any pre-arranged wave length, and is further provided with a change-over switch permitting an instantaneous change of the circuit from a highly syntonised tuned condition to an untuned condition (for standing by). This arrangement has been especially devised for picking up incoming signals of widely different wave lengths. By reason of its robust nature the magnetic detector may be kept permanently connected to the transmitting aerial, thus dispensing with all mechanical change-over switching arrangements between the transmitting and receiving circuits. Further, in conjunction with the short-circuiting contacts on the manipulating key, it allows the operator to be interrupted during the transmission of a message in the event of there being erroneous reception at a corresponding station. A suitable testing buzzer is provided and is kept permanently installed for the purpose of instantaneously testing the receiving circuits, and a tuning lamp and adjustable choking coil are also permanently installed for the purpose of indicating the condition of syntony of the transmitting circuits, while a wave-meter, covering the full range of the transmitting circuit is supplied. The Marconi Apparatus is shown in Figs. 19 and 20.

The bell installation comprises no fewer than 1,500 pushes, which, in the staterooms, are for the most part grouped with the switches for controlling the lights on combination plates placed within convenient reach of each berth.

In conclusion, we would express our indebtedness to Messrs. Harland & Wolff for the information given above and to our contemporary "The Shipbuilder" for the loan of the blocks of Figs. 1, 3 and 12.

MODERN DIESEL OIL ENGINES.*

BY F. SCHUBELER.

Summary.—The author gives a short survey of the practical development of the Diesel engine up to the present time and its applications to various forms of driving.

As is already known, it was the intention of the inventor of the Diesel engine to burn coal direct in the working cylinder, which, however, proved to be impossible, as the unburned residues could not be removed from the latter. For dealing with liquid fuel the propositions made by different designers varied principally only in the arrangement of the air-pump and the construction of the fuel valve. For instance, Haselwander and Trinkler used the working cylinder, so to speak, as the first stage of the air-pump by extracting air during the compression stroke from the former as soon as a certain pressure (about 100 lb.) was reached, and only producing the differential pressure for the injection air (700 lb. to 900 lb.) in the actual air-pump. Haselwander had his air-pump combined direct with the working piston by a differential arrangement, whereas Trinkler provided a special air-pump in the cylinder cover. Other designers proposed an intermediate process between those of the ordinary gas engine and the Diesel engine. Thus Sabathé advocated compression up to about 300 lb. and artificial ignition of part of the fuel. The Brons motor, as still made by the Gasmotoren-Fabrik Deutz in the smaller units, has similar features. Generally, however, it can be stated that most of the above-mentioned propositions have disappeared and some have not even been carried out, all of them giving place to the well-known Diesel principle with its characteristics: compression in the working cylinder up to the ignition temperature of the fuel (about 500 lb. or about 1,000 F.), and creation of the pressure of the injection air (600 lb. to 850 lb. per square inch), by means of which the fuel is introduced atomised into the cylinder by an independent multiple-stage air-pump. It is only natural that the development of this principle should have caused some initial difficulties. In the hitherto-known steam engine the working process takes place partly in the boiler and only partially in the working cylinder. The boiler, which has no moving parts, deals with the heaviest part of the process and furnishes the working fluid in a refined state to the working cylinder, whereas with the Diesel engine the whole process has to be dealt with in the working cylinder. That it has been possible within a comparatively short period to develop the Diesel engine to such a degree as to enable it to compete successfully with the steam engine in large units certainly proves the present-day skill and thoroughness of engineering. It may be stated that as regards reliability the Diesel oil engine can now be considered as fully equal to the steam engine, it being only a question of economy in each individual case which of the two prime movers takes the preference. There was one principal difficulty which had to be overcome. The extremely high pressures and temperatures of the Diesel process put a limit to the dimensions of the cylinders, which hardly exceed a diameter of 30 in. This corresponds to an approximate cylinder output of 300 H.P. to 400 H.P., assuming 150 revs. per min. of the shaft and the ordinary Otto cycle. Theoretically there would be nothing to prevent any desired output being obtained by arranging any number of cylinders side by side. Practically, however, it is not advisable to provide for more than six cranks, as a larger number would produce an inadmissible twisting of the shaft. Furthermore, such units require a great amount of space and would become extremely costly. These reasons called forth the necessity of seeking other means by which to increase the specific cylinder output of the ordinary single-acting Otto cycle engine.

There are the following possibilities: (1) By carrying out the single-acting Otto-cycle machine as a double-acting one. (2) By adopting the single-acting two-stroke cycle working process. (3) By adopting the double-acting two-stroke cycle working process. The double-acting Otto-cycle cylinder under (1) corresponds approximately to a doubling of the cylinder output. Almost the same result can be obtained by the procedure under (2), which, however, necessitates the provision of special scavenging pumps. The solution under (3) would theoretically quadruplicate (practically about 3-4) the output of the ordinary Diesel engine cylinder and mean the adoption of the usual working process of steam engines for the oil engine.

* Abstract of a Paper read at the meeting of the Institution of Mechanical Engineers at Zürich.

Digitized by Google

For smaller and medium size units the single-acting Otto cycle is the preferable, as it involves the smallest working strain on the cylinder. Although this type of engine necessitates a more or less frequent cleaning of the internal parts especially of the exhaust valves, the author is informed that such machines have worked for periods of six to eight weeks without interruption, even in cement factories and mills.

As the main advantage of the two-cycle engine it may be mentioned that the turning moment is much more favourable, and consequently the revolving masses for obtaining a certain degree of cyclic variation are much lighter. The two-cycle engine furthermore guarantees better starting and better conditions for regulation, which is specially important for direct coupling with alternators. The space required is considerably smaller and the engine is also lighter and, therefore, cheaper. The difference in price between an ordinary single-acting four-cycle and a single-acting two-cycle engine for a capacity of 1,000 H.P. amounts to about 25 to 30 per cent., which figure would have to be considerably increased if larger units were compared. Furthermore, the lubricating-oil consumption is somewhat smaller per horse-power, as the same cylinder and bearing dimensions are sufficient for producing about double the output.

It still remains for reference to be made to the chief advantage of the two-stroke engine—that is, the elimination of the exhaust-valve. Some difficulties cannot be avoided when the latter is used in large sizes. Generally speaking, the fewer working parts coming into contact with the hot gas the better. The scavenging valve (or valves) in the cylinder cover may be dispensed with. Only a part of the cylinder slots are then used as exhaust slots, the remainder on the opposite side being used for the introduction of the scavenging air. A special shape is given to the top of the piston to guide the current of scavenging air and to guarantee a thorough removal of the burnt gases. The scavenging valve is thus removed from the high temperatures, only the fuel valves and starting valves being so exposed.

It is self-evident that for the continually advancing engineer the problem of the double-acting Diesel engine is attractive, especially as he already has excellent models in the gas engine, for which the stuffing-box problem may be regarded as solved. On the other hand, it must be admitted at once that with the Diesel engine the conditions to be dealt with are much more unfavourable. It will, therefore, be preferable to avoid the difficulties with the stuffing-box in the first instance, and to develop the new type on the lines of the single-acting four-stroke cycle engine, with which the gain in output is practically the same. To pass at once to the double-acting two-cycle engine without first gaining experience with the single-acting engine seems to the author not to be the course of natural development and to be somewhat risky. As to the design of an engine of the latter type—namely, the double-acting two-stroke engine—the provision of a special cross-head and also the horizontal arrangement is recommended. This being so, it may be deduced from gas-engine and steam-engine practice that for the support of the pistons a rear stuffing-box with a bearing support for carrying the weight of the pistons has to be provided, which is certainly far from desirable. In addition, great inconvenience is caused by the piston-rod having to pass through the combustion chamber and necessitating an eccentric introduction of the fuel. The combustion process must, therefore, be far more unfavourable, and the construction of the valve gear more complicated. The proper setting of the two compression clearances on both sides of the piston is not as simple as with the single-acting engine, where by a shortening or lengthening of the connecting-rod the compression can be proportioned to any amount desired. With the double-acting machine a compromise has always to be made, and the length of the piston-rod has to be provided for an average compression on both sides.

The different working conditions of the Diesel oil engines naturally require different types. The piston speed is generally between 600 ft. and 1,000 ft. per minute, which cannot be reduced below a certain limit, as otherwise the slightest leakage could prevent the compression attaining the required amount. This is especially important for marine Diesel engines when they are being run dead slow. The piston speed can, however, be as low as 180 ft. to 200 ft. per min. for continual service.

For standard slow speed single-acting four-cycle engines the number of revolutions lies between 150 and 300, with outputs between 1,000 H.P. and 15 H.P. These engines have the best fuel consumption, but have also the disadvantage that they are heavy and expensive. For this reason a single-acting multiple cylinder high-speed four-stroke cycle engine was built which is especially suitable for direct coupling to dynamos. The speed varies between 220 and 350 revs. per min. for sizes varying between 1,000 H.P. and 100 H.P. These high-speed types, if suitably designed and carried out by first-class manufacturers, are just as reliable in service as the slow-speed types. They have, however, a slightly higher fuel consumption. On account of their smaller first cost they are especially suitable where the Diesel engine is intended as a stand-by. For very small auxiliary engines up to about 100 H.P. on board ship the speeds are still higher, and range from 400 to 600 revs. per min. and even higher.

Single-acting two-stroke engines with outputs ranging between 700 H.P. and 3,000 H.P. are built with speeds between 160 and 140 revs. per min.

For ship propulsion there is a tendency to use lower speeds in order also to obtain a good propeller efficiency. To give some figures, 100 to 350 revs. per min. may be taken as limits for sets of several 1,000 H.P. down to 100 H.P.

Following this course, the normal four-cycle Diesel engine was first adapted for marine purposes, and there are several boats running with such engines. This type, however, having, as already mentioned, a limited output and being moreover heavy, has the further disadvantage that the most essential feature of the marine engine—namely, the problem of direct reversibility—cannot easily be solved. For smaller crafts the propeller can be made reversible, or a special reversing gear can be fitted to the shaft, similar to those used in motor cars. Another possibility is to generate with a normal non-reversible Diesel engine electricity in a generator, and have the propeller coupled to an electric motor, which can easily be made reversible. This system, the so-called Delproposto system, which otherwise gives good results, is not very economical on account of the numerous transformations of energy. It is also rather complicated, expensive and heavy. The first boat of this type is the steamer "Vandal" on the Volga, carried out by Messrs. Nobel. A similar Diesel boat, the "Venoge," was built by Sulzer Brothers in 1904, for the Lake of Geneva. The engine has an output of 100 H.P. Another inconvenience of the four-stroke cycle type is the presence of exhaust valves, which necessitate a more or less frequent cleaning.

These difficulties, including also the last-mentioned one with the exhaust-valves, could be overcome by adopting the two-cycle engine. A number of boats fitted with such engines, with outputs up to about 1,000 H.P. are in service. The reversibility can easily be attained. It may be mentioned that Messrs. Sulzer Brothers have done the pioneer work in exhibiting the first engine of this type at the Exhibition of Milan in 1906. For outputs below 1,000 H.P. these engines may be of the ordinary trunk-piston type, whereas for larger units crossheads should be provided. The appearance of such an engine does not differ considerably from that of the well-known steam marine engine. Some firms have already gone further, claiming to be able to carry out a double-acting two-stroke machine. Unfortunately, the results obtained with such engines are unknown to the author, and a definite decision—whether single-acting or double-acting engines are most suitable for marine purposes—cannot be given for the time being. The author for his part feels somewhat doubtful whether success has already attended such efforts. Preferably a two-propeller arrangement is adopted, and with larger units the scavenging-pumps will be separated from the propulsion-engines and driven by independent non-reversible Diesel units.

The space required for marine Diesel engines is smaller than for steam plants, the difference amounting to about 30 to 50 per cent., and the saving in weight is also considerable, reaching as much as 50 per cent. With marine Diesel engines it is possible to attain a larger action radius for ships, which can be five to six times as large as that for ordinary steamboats.

Regarding other applications of the Diesel engine, attempts have been made to build also Diesel locomotives, but the author regrets not being in a position to furnish any information. The adoption of the Diesel engine for motor-cars and aeroplanes does not seem to be very promising on account of the high pressures and consequent heavy and expensive constructions, not only for the engine but also for the accessories. One word is required as to the thermal conditions of the engine. The calorific efficiency, respective mechanical output, may attain 30 to 40 per cent.; 25 to 30 per cent. are lost in the cooling water and the rest is contained in the exhaust gases. Of the latter heat about 20 per cent. can eventually be utilised for heating purposes, and in adding also the heated cooling water the total efficiency of a Diesel unit may go up to 80 per cent., which is certainly remarkable. With regard to the actual costs per brake-horse-power hour, in assuming a fuel price of 50s. per ton (which is certainly an outside figure) this will amount to about 0·11d. to 0·13d., or about 0·16d. to 0·2d. per kilowatt-hour. These figures are the actual figures maintained during actual service, assuming, of course, that the engines are kept in good condition. The author hopes that the discussion will raise other points of general interest, which are omitted in this Paper, or throw further light on others mentioned therein.

SINGLE-PHASE ELECTRIC LOCOMOTIVE FOR THE COMPAGNIE DU MIDI, OF FRANCE.

Towards the end of the year 1908 the Compagnie du Midi, of France, decided to adopt electric traction on a large portion of its system, and with this object in view determined to open an experimental line on the track between Villefranche, Vernet-les-Bains and Marquixanes. At the beginning of the year 1909 the railway company, therefore, placed an order with the A.E.G. for the construction of an experimental electric locomotive to be built in accordance with its specification. The

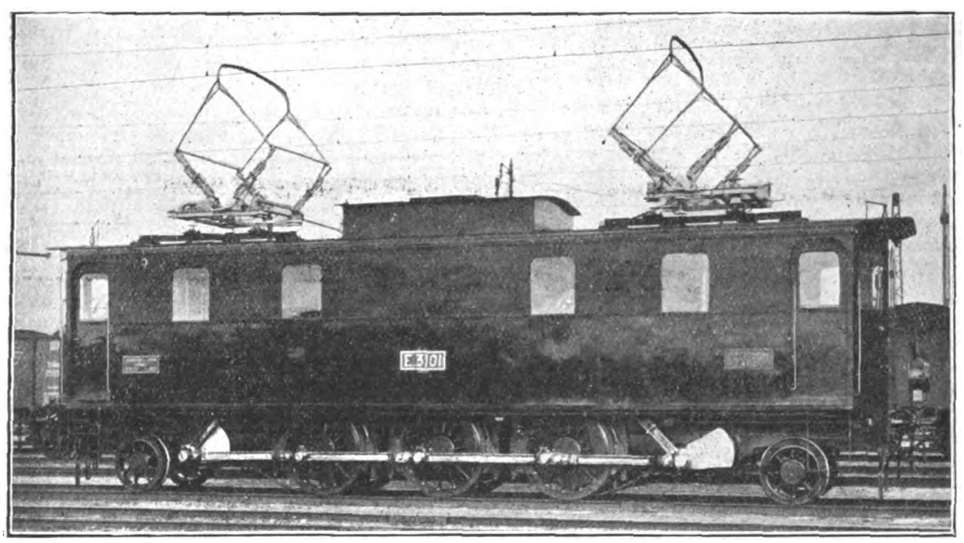

FIG. 1.—A.E.G. SINGLE-PHASE ELECTRIC LOCOMOTIVE FOR THE COMPAGNIE DU MIDI.

principal details with which it was necessary to comply were the following :—

Gauge	1,435 mm.	...	3 ft. 10 in.
Diameter of driving wheels	1,310 mm.	...	3 ft. 6 in.
Diameter of running wheels	850 mm.	...	2 ft. 9 in.
Diameter of crank circle	540 mm.	...	1 ft. 5 in.
Length of loco. over buffers	13,140 mm.	...	43 ft.
Greatest width	3,150 mm.	...	10 ft. 3 in.
Greatest height from the ground	4,250 mm.	...	14 ft.
Total wheel base of the loco.	9,600 mm.	...	31½ ft.
Side play of running axles	55 mm.	...	2·16 in.
Side play of centre axles	20 mm.	...	0·8 in.
Fixed wheel base	3,600 mm.	...	11·8 ft.
Pressure on driving axles	18 tons	...	—
Pressure on running axles	15·5 tons	...	—
Total weight	85 tons	...	—
Adhesive weight	54 tons	...	—
Minimum curve radius	160 m.	...	525 ft.
System of supply	Single-phase current	...	—
Overhead line tension	15,000 volts	...	—
Frequency	16⅔ cycles	...	—
Motor hourly rating	2×800 H.P.	...	—
Maximum speed	75 km. per hour	...	46 miles per hour
Max. tractive effort at drawbar	12,500 kg.	...	12·5 tons
Tractive effort at drawbar during one hour	8,000 kg.		8 tons

The locomotive was designed by the A.E.G. in conjunction with the locomotive builders, Henschel & Son, of Cassel. The two motors work with the driving rod set at an angle of 45 deg. to the horizontal on two intermediate crank shafts placed outside the driving axles. As no counter movement takes place between the inclined and horizontal coupling rods, both coupling rods could be arranged in a vertical plane. By this arrangement the crank pins for the intermediate crank shaft can be made shorter, and at the same time are not subjected to such heavy stresses.

By arranging the two motors and the main transformer in the centre of the locomotive the moment of inertia of the locomotive is kept comparatively small. This is of importance, as the fixed wheel base of the locomotive, which was specified by the railway company, is only 3·6 metres (11·8 ft.). In order to ensure flexibility of the locomotive on curves, running axles with radial adjustment towards the centre point of the curve were adopted, which allow the locomotive to travel over curves having a radius of 160 metres (525 ft.) without rocking.

For carrying the main frame and leading the running axles back to the central position a laminated spring is used, which, in the central position, has a tension of 2,400 kg. (2·4 tons), and for greater deviations about 4,800 kg. (4·8 tons). In order to obtain flexibility on curves, only the two outer coupling axles are rigidly fixed to the frame. The centre coupling axle has a side play of 20 mm. (0·8 in.) on each side, so that it can run on the outer rails on sharp curves, and is thus guided independently of the frame. The locomotive is guided by the two front axles on curves having a radius of not less than 250 metres (820 ft.). On curves of less than 250 metres (820 ft.) radius the leading coupling axles are drawn off the outer rail; the guiding of the locomotive is then effected by the front running axles only. The suspension springs are so arranged that the locomotive is supported at six different points. Each running axle is connected to the adjoining coupling axles by means of a bell crank. The centre coupling axle has separate springs, spiral springs being provided for the suspension of the frame instead of leaf springs. The ends of the coupling rods are provided with bushes which are not adjustable. This simple form of construction has already given good results on numerous railways. The motor bearings and intermediate crank-shaft bearings may be adjusted for wear.

The upper part of the locomotive is completely enclosed. The main transformer is mounted in the centre of the locomotive on double "T" iron girders arranged between the main frame covers, and strengthened by strong iron supports. The high-tension oil switch and a part of the controlling gear are mounted on a special frame immediately above the transformer. The central part of the locomotive roof may be opened, and for this purpose is provided with doors and hinges. By this arrangement the high-tension oil switch can be taken out, or the contactors inspected without entirely removing the roof. The main transformer may also be taken out after the removal of the contactor casing and the central part of the roof. On the right and left-hand sides of the main transformer the two motors are mounted on cross-girders fixed to the main framework; they may also be removed from above.

The two A.E.G. Winter-Eichberg motors employed, each having an hourly rating of 800 H.P., are constructed in the open form. They have 14 poles and are excited through the rotors. All brushes are conveniently accessible owing to the open form of construction adopted for the motors. The stators are wound with a single-phase lap winding. At high speeds the portion of this winding which lies in the reversing zone is connected to a part of the exciter transformer circuit by means of special contacts, in order to ensure good commutation at these speeds. The stators are rigidly bolted to strong cross-girders. The rotors run in amply dimensioned bearings having pad lubrication. The bearings are not directly connected to the stators, but are bolted to the longitudinal girders on the lower frame. In order to allow convenient access to the commutators, no bearing shields are used. The frames are stiffened at the bearings by steel castings which are riveted to the locomotive framework.

It should be specially mentioned that within speed limits of 30 km. to 55 km. (18·6 to 34 miles) per hour current can be returned to the line when travelling on down grades.

Digitized by Google

The cranks for the motor shaft work in sheet-metal cases, which are only open below in order to allow the driving rod to pass through to the intermediate crank shaft. Between these cases, which may be easily opened for the inspection of the crank pins, and the outer wall of the locomotive ample space is allowed for the attendant to pass from one part to another. The drivers' cabins are situated at each end of the locomotive, and are fitted with all the necessary measuring instruments and driving gear. The remaining electrical apparatus is mounted in the machine compartment. A gangway on one side of the locomotive gives access from the driver's platform to all the apparatus. Two brakes are used, one being an automatic compressed air brake of the Westinghouse type, and the other a hand-operated brake. The coupled axles are braked on both sides in such a manner that 60 per cent. of the rail pressure of the driving wheels—*i.e.*, $0{\cdot}6 \times 54 = 32{\cdot}4$ tons—is braked. The locomotive is fitted with two speed indicators of the "Hausshalter" type, compressed-air sand strewers and whistles, petroleum signal lamps, and the other customary signalling devices and tools. Gangways at the ends allow the attendants to pass from the locomotive to the trains. Our illustrations show a general view of this locomotive and detailed drawings.

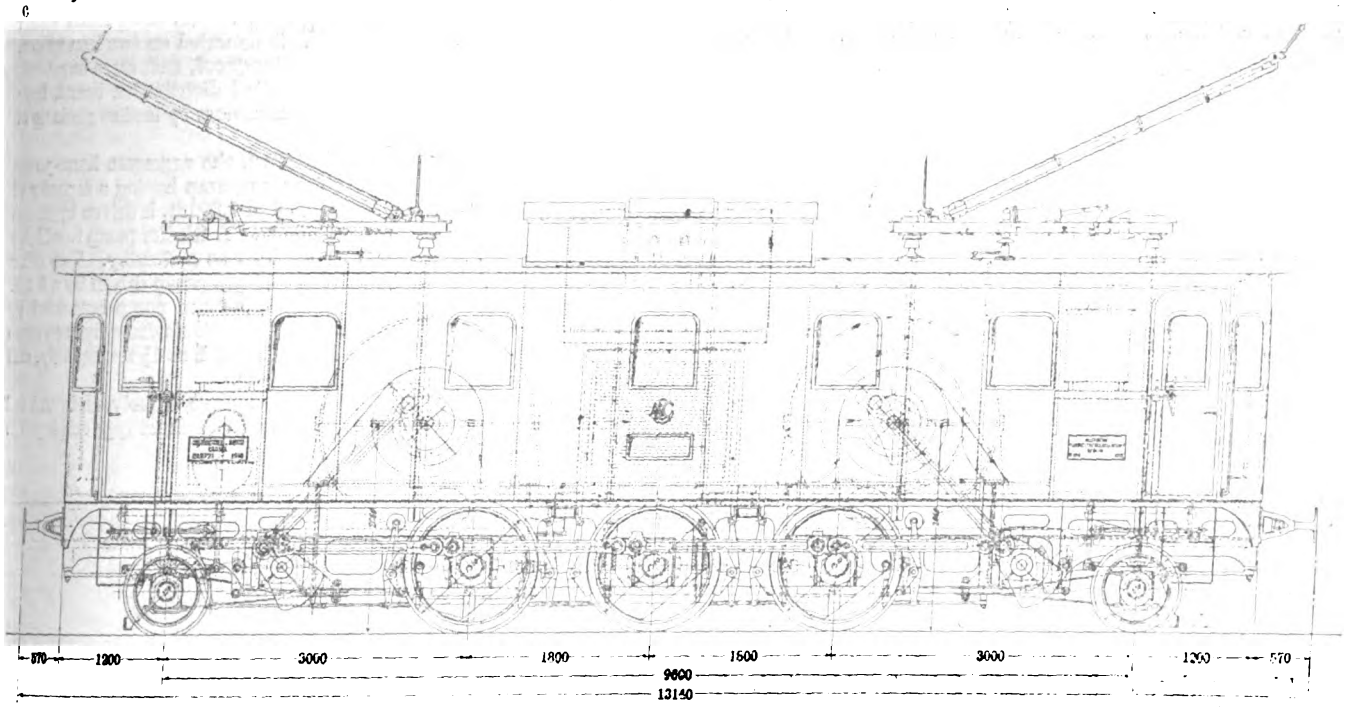

FIG. 2.—SIDE ELEVATION OF THE MIDI LOCOMOTIVE.

It should be mentioned that the locomotive is fitted with a pantograph collector, as shown in the photograph, and not with collectors of the ordinary bow type.

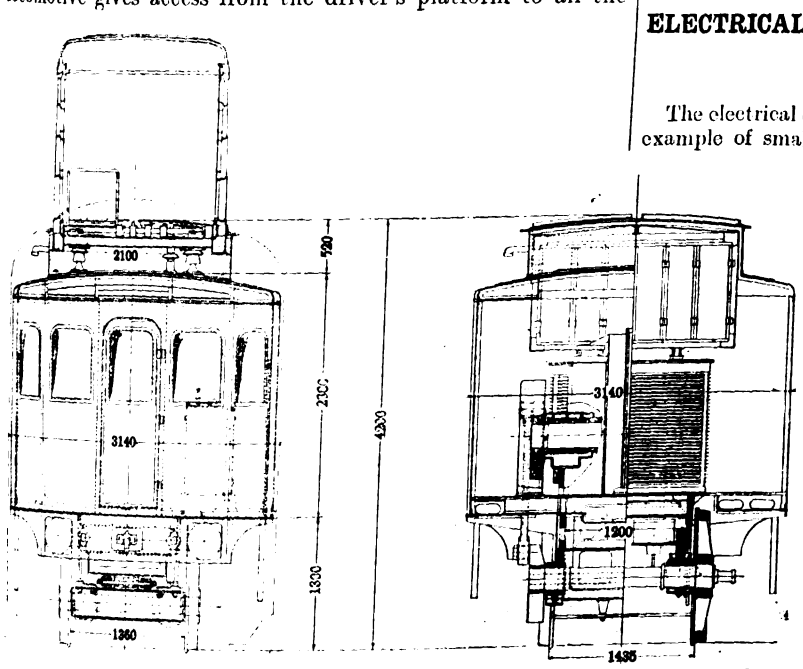

FIG. 3.—END VIEW AND SECTION OF LOCOMOTIVE, SHOWING COLLECTOR IN ITS UPPER AND LOWER POSITIONS.

ELECTRICAL EQUIPMENT OF THE SNEYD COLLIERY, BURSLEM.

The electrical equipment of the Sneyd Colliery, Burslem, is another example of small beginnings leading to satisfactorily large endings. The following details will doubtless be of interest at the present time when the whole position of electricity in mines is being attacked by interested persons.

Twenty years ago, this Company laid down a small lighting set to light their offices. Eight years later they put down a 50 kw. three-phase Westinghouse generator set for power purposes. This set operated two haulage systems (a 20 H.P. main and tail, and a 20 H.P. endless rope), and a 30 H.P. pump. It was something in the nature of an innovation, being one of the very earliest applications of the three-phase system to collieries in this country, but it proved so successful that the company decided to convert all the haulages in their mines, and for this purpose built their present power station.

The plant next installed consisted of two 250 kw. Howden high-speed engine sets, running at 375 revs. per min. direct coupled to three-phase 25 frequency 440 volt alternators, with exciters separately driven by small steam sets, plenty of space being left for extensions. In its two years of service this plant showed so many economies and advantages that it was further enlarged by the installation of a 500 kw. turbo-alternator. This turbine is of the Rateau type and runs on exhaust steam from the winding engines, with a thermo-accumulator interposed, and drives a British Westinghouse three-phase 25 frequency 440/500 volt turbo type alternator, with coupled exciter, the set operating at 1,500 revs. per min. Steam is supplied to the engine sets by three Babcock & Wilcox and six Lancashire boilers working at 120 lbs. and 90 lbs. pressure respec-

Digitized by Google

tively, the Babcock & Wilcox grates being designed to burn the fine slack from the screening plant.

The switchboard is mounted on a platform at one end of the station and comprises three generator and four feeder panels, fitted with the usual meters, overload circuit breakers, &c., the rheostats for voltage regulation being placed at the back of the board, though they are operated from pillars in front. The supply is led to the various motors installed on the surface, and to the top of the pit shafts by underground cables, and thence down the pit to sub-stations.

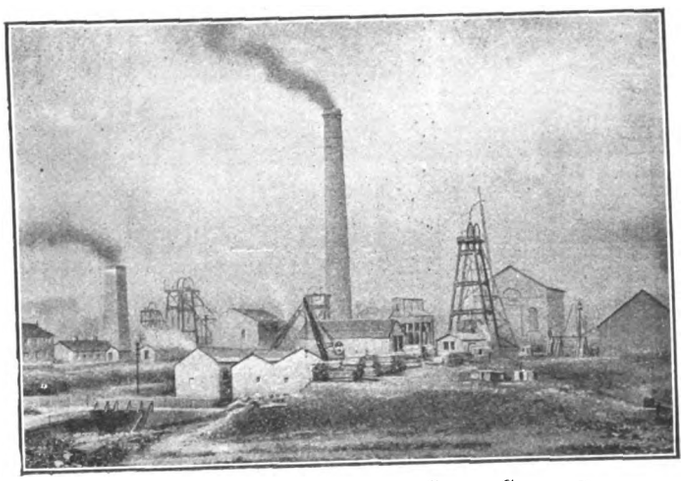

FIG. 1.—GENERAL VIEW OF SNEYD COLLIERY.

There are three pits known as No. 2, No. 3 and No. 4, the electrical machinery in No. 2 pit comprising 11 motors, totalling about 380 H.P., all engaged either in haulage or pumping work. The main haulage to the pit bottom is a single drum set, capable of dealing with six tubs per wind, each tub carrying approximately 12 cwt. of coal. These are hauled up a gradient of 1 in 3 for a distance of 160 yds., the motive power being furnished by 100 H.P., 440 volt, Westinghouse slip ring motor, running at 475 revs. per min., and driving by ropes to the haulage pulley, which transmits the power through a friction clutch and helical gearing to the drum, the haulage ropes being ¾ in. steel wire.

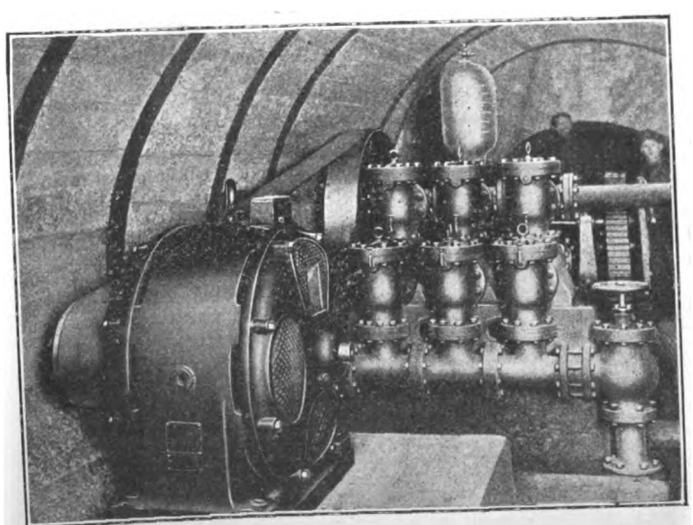

FIG. 2.—30 H.P. WESTINGHOUSE MOTOR DRIVING THREE-THROW SCOTT-MOUNTAIN PUMP AT SNEYD COLLIERY.

The control for this unit is effected by means of an oil immersed reversible controller. There are also the following haulage gears in this pit:—One 75 H.P. single-drum gear drawing nine waggons up an incline of 1 in 4½. One 75 H.P. endless rope plant, and three 20 H.P. single-drum haulage sets. The latter are semi-portable, the gears, motor, controller and resistance all being fixed in the same bed plate.

The sump at the pit bottom is furnished with two three-throw pumps, each having a lift of 750 ft. These are driven by a 30 H.P. squirrel-cage motor running at 710 revs. per min. through an 8 in. canvas belt, one being kept as a spare whilst the other is in use. Three small pumps each driven by a 3 H.P. motor act as an auxiliary plant.

The distribution switchgear supplying these motors is situated at the pit bottom, and current is led by three single-core cables to 'bus-bars at the back of the distribution board. The feeder switches are of the totally enclosed, automatic, oil immersed type, specially designed for mining work, the necessary meters being fitted within the casing of the switch. The gear is mounted on two iron pillars, and forms a complete dust proof, water-proof, and, more important still in colliery work, gas-tight, iron-clad distribution board, from which the current is led to the various motors by feeders made up of three-core armoured cables.

In No. 3 Pit six motors are installed, the aggregate horse-power amounting to 333. A three-throw ram pump having a capacity of 200 gallons per minute against a head of 1,200 ft. is driven by means of ropes from a 100 H.P. slip ring motor. A Riedler pump to which a motor of 75 H.P. is attached is provided as a standby. Two other pumps act as auxiliaries, viz., a centrifugal pump driven by a 5 H.P. motor, and a small portable three-throw ram pump connected by gearing to a 3 H.P. motor. There are two single drum haulage gears drawing waggons up incline of 1 in 3, and 1 in 4½ respectively, and both operated by 75 H.P. slip ring motors.

In No. 4 Pit there are two types of haulage, namely, main and tail and endless rope, which differ from the single drum type employed in No. 2 and No. 3 Pits.

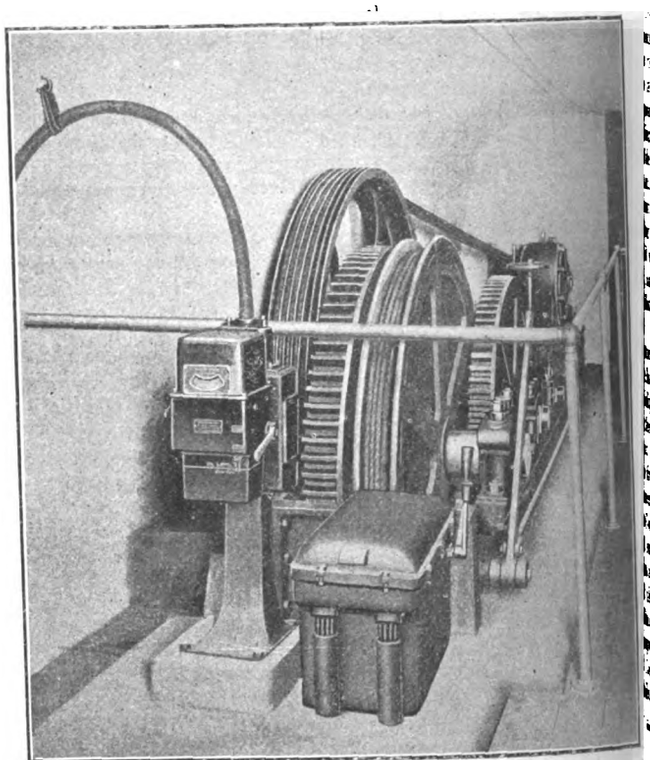

FIG. 3.—20 H.P. WESTINGHOUSE MOTOR DRIVING ENDLESS HAULAGE GEAR AT THE SNEYD COLLIERY, BURSLEM.

The single drum, as its name implies, consists of a single drum winding a single rope, and, therefore, the gradient must be steep enough to allow the tubs to draw the rope back by gravity; in the main and tail type, however, the main rope hauls the full tubes, and the tail rope takes back the empties. In No. 4 Pit there are two of these haulages, both driven by 75 H.P. motors, each capable of dealing with 30 trucks at an average speed of 5 miles per hour.

In the endless rope type of haulage the rope is passed two or three times round a "C" Pulley, and then round a guide wheel at each end of the road, the tubs being affixed to the rope by clips. It will be seen that to allow of the use of this type the road must be wide enough to allow two tubs to pass each other at any point on the route. In this particular case a 20 H.P. squirrel-cage Westinghouse motor drives the haulage pulley by ropes, thence by pinion and spur wheel to the "C" pulley. The switchgear operating the motor consists of a totally enclosed oil switch, similar to those used on the distributing board, and an oil immersed controller. All the haulages in the mine are fitted with strong brakes of the band type. There are also two single-drum haulages in this pit, driven by 20 H.P. slip ring Westinghouse motors, and controlled by tramway type controllers dealing with four tubs on a 1 in 4½ gradient.

Digitized by Google

Two 5 H.P. squirrel-cage motors are used to operate creepers, one for raising loaded tubs and the other empty tubs, both working at the pit bottom. One motor of 50 H.P. drives a two-stage air compressor by means of a belt, the air being used for percussive drills, and two small haulage winches.

Hydraulic rams are used to push the full tubs into the cage, and at the same time push the empties off, a three-throw pump driven by a 10 H.P. motor supplying the water pressure. This is a most useful device, and saves a great amount of time and labour in getting the coal to the surface. The total horse-power of the 10 motors working in this pit is 300. The cages are of the four deck type, capable of carrying 8 tubs of coal per wind, and are operated by 2,000 H.P. steam winding engines working at 90 lbs. steam pressure.

On arriving at the surface electricity is again requisitioned to convey the coal to the screens, as well as in the actual operation of screening. At the pit brow there is a 20 H.P. motor driving a creeper by pinion and spur wheel, which is capable of pulling the loaded waggons up the incline to the screen, into which the coal is tipped by power-driven tipplers.

The principle of screening is so well known that it hardly needs description, and it will suffice to say that the screens are large rectangular sieves, placed on a slant, and shaken by eccentrics, the latter being driven by a 150 H.P. motor. As the coal drops through the screens, it is conveyed on belts to the shutes, the dirt being picked out by boys, and carried away by a small conveyor belt, known as the dirt belt. There are altogether five 5 H.P. Westinghouse motors operating these belts, and a 10 H.P. motor controlling the hoisting gear for raising the jib ends of the belt, and so minimising the breakage of coal falling from the belts. An interesting feature of the screens is the installation of Westinghouse Cooper-Hewitt mercury-vapour lamps, the light from which is admirably suited for coal picking. A fan driven by a 20 H.P. motor extracts most of the dust and delivers it in a "Maxanor" apparatus when it is mixed with water and allowed to settle, the sediment being afterwards dried and burnt in the boiler fires.

In the fitting shops a 3 H.P. squirrel-cage Westinghouse motor is doing splendid work, driving line shafting from which three lathes, a radial drill, and drilling machine, and a 6 ft. by 2 ft. planner are operated, whilst in the next shed a 20 H.P. motor drives a 4 ft. circular saw.

Electric motors are also used to operate the blacksmith's shop and the crane, the latter being worked by two motors, a 20 H.P. British Westinghouse slip ring motor for hoisting, and a 6 H.P. 110 volt direct-current motor for slewing the crane.

There are at present 53 motors installed, totalling 1,440 H.P., varying in size from a small 3 H.P. pump motor to a 150 H.P. motor driving the screens, all at work, saving time, labour, and, therefore, money for the Company.

The gradual extensions of this plant from a lighting set to an installation with a 1,000 kw. output, is, we think, proof more eloquent than words of the efficiency and economy with which electricity meets the conditions experienced in colliery work.

We have to express our indebtedness to Mr. Jno. Gregory, manager of the Sneyd Collieries, for permission to publish the foregoing interesting details.

ELECTRICITY SUPPLY IN THE CITY OF LONDON.

The annual report of the engineer to the City of London (Mr. Frank Sumner, M.Inst.C.E.) for the year 1910, which has just been issued, says:

The lighting of most of the main thoroughfares by arc lamps was continued throughout the year. The number of original type open electric lamps in lighting at the end of the year, at a cost of £26 each, was 334, a decrease of 32, which is accounted for by the substitution of the new and cheaper flame arcs in West Smithfield, and their removal from several thoroughfares in connection with the experimental lighting. The 18 Beason enclosed arcs were also removed. In addition, there were 80 Oliver flame arcs (partly experimental) and 36 metal filament lamps (experimental) in lighting during the year. The arc lamps in use at Dec. 31 included 334 of the original type open lamps and 59 Oliver flame arcs, at £17. 10s. per lamp per annum, supplied by the City of London Electric Lighting Co., and 10 Oliver centrally hung flame arcs in Cannon-street (experimental), at £17. 10s. per lamp per annum, supplied by the Charing Cross Co. In addition, there were 21 experimental arcs and 36 experimental metal filament lamps, making a total of 460 lamps. The metal filament lamps included 16 75 c.p., 10 100 c.p., 5 200 c.p., 3 600 c.p. and 2 600 c.p. The extra cost of electric lighting on dark and foggy days (27 days) was £182. 12s. 11d. The total number of defective lamps reported during the year was 89, including 9 of the experimental lamps in Cannon-street.

In the case of the gas lighting the defective lamps appear to be in a much larger proportion, the number of lamps in use being 2,659, the number of lights that failed 42 and the number of "feeble lights" 1,721.

The length of subways under the control of the Corporation is 1 mile 947 yds., and the mains and conduits therein include 1 mile 1,481 yds. owned by the City of London Co., 1 mile 1,721 yds. owned by the Charing Cross Co., 2 miles 1,230 yds. of mains and conduits for telegraph and telephone purposes, and 1 mile 1,353 yds. of pneumatic tubes owned by the G.P.O.

There are 52 police ambulance call posts and 50 fire-alarm call posts, besides one on private property and two just outside the City boundary.

Since March 26, 1903, it has been a condition that new clocks overhanging the public way shall be synchronised according to Greenwich time, and 13 such clocks have been licensed. Only 33 of the 102 private clocks observable from the public way are synchronised, and none of the 29 church clocks.

Since 1899 a total of about 25 miles of derelict overhead wires have been removed. During the past year 7 miles 508 yds. were removed as the result of 126 notifications by the Corporation. The system of identifying the owners by having the wires labelled has proved of great advantage. It has been found that large numbers of wires have been erected without notice. The number of private owners of lines is 141 and the number of companies owning lines is 26. The National Telephone Co. have about 735,136 spans across public thoroughfares, compared with 733,956 last year and 260,000 in 1899.

Although the exchange telephone systems of the National Telephone Co. and the Post Office have been greatly extended, there is a demand for private direct lines. The necessity of an immediate connection for business purposes is one cause of this increase, and there is nothing to prevent such lines being erected by wiring contractors for firms having premises in more than one part of the City, or between one or more different firms, subject, in the latter case, to license from the Postmaster-General.

Great inconvenience was caused, as in previous years, by the laying of services and the frequent and long-continued opening of the street boxes giving access to the conduits and cables in connection with the "Telephoning London" system, and no less than 2,154 notices were given during the year by the General Post Office authorities to open manholes for repairs, exclusive of inspection; 307 new services were laid and several new boxes constructed. This Department proceeded with the laying of several new conduits and ducts in various parts of the City, which necessitated the disturbance of about 2 miles of public ways, with the resultant inconvenience to the general public, although in every instance the regulations were abided by. The City of London Electric Lighting Co. gave notices for laying 225 services and the construction of 35 new boxes in connection with the supply of electrical energy to premises, and the Charing Cross Co. gave 144 notices for laying services. The London Hydraulic Power Co. gave 30 notices for laying on services from and extensions to existing mains.

THE PACIFIC CABLE.

A Bill (backed by the names of Mr. Hobhouse and Mr. J. A. Pease) has been introduced into the House of Commons whose object is to extend the Pacific Cable Act, 1901. The text of the new Bill is as follows:—

1.—(1) The Pacific Cable Board may, with the approval of the Treasury, apply out of their reserve fund such sums as may be required for the purpose of any works authorised under this Act: Provided that the sums standing to the credit of that reserve fund are not at any time thereby reduced below the sum of £100,000; and that the Pacific Cable Board shall pay to the reserve fund, as part of the annual expenses of the Pacific cable in each year, in accordance with regulations approved by the Treasury, such sums as may be sufficient to repay any moneys so applied in 35 years, with interest at the rate of 3½ per cent. per annum.

(2) Sections 3 to 7 of the Pacific Cable Act, 1901, shall be read as if references to the Pacific Cable included references to any works authorised under this Act, and as if references to the payment of annuities created under that Act included references to payments to the reserve fund required under this Act.

2.—(1) The works authorised under this Act are a submarine cable between Australia and New Zealand, as already sanctioned by the contributing Governments, and any other extensions, connections or re-arrangements in or near the Pacific Ocean which, in the opinion of all the contributing Governments, are necessary or expedient for the improvement of the Pacific Cable Board's undertaking.

(2) The reserve fund means in this Act the reserve fund established under the authority of the Treasury by the Pacific Cable Board.

(3) The contributing Governments mean in this Act the Governments represented on the Pacific Cable Board—namely, His Majesty's Government, the Government of Canada, the Government of the Commonwealth of Australia, and the Government of New Zealand.

3.—This Act may be cited as the Pacific Cable Act, 1911.

New Radium Institute.—The new Radium Institute in Riding House-street, which is the outcome of the munificence of Lord Iveagh and Sir Ernest Cassel, will, it is announced, be opened on August 14th, and will be equipped with £50,000 worth of radium. Only patients recommended by members of the medical profession will be admitted.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.
Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d.

RAILWAY ELECTRIFICATION IN SWITZERLAND.

It is appropriate that the meeting of the Institution of Mechanical Engineers at Zürich last month should have been marked by the presentation of a lengthy Paper by Mr. E. HUBER-STOCKAR on "Electric Traction in Switzerland." Our readers will find an abstract of this Paper, necessarily very much abbreviated, elsewhere in this issue. It is only natural that electric traction should make very considerable progress in Switzerland for the reason that on the one hand there is abundant water-power, and on the other hand there is a total absence of native coal, all such fuel having to be imported. At the same time, although many of the Swiss railways are run by the State, it is nevertheless sought to work these (and still more those owned by companies) at a profit, and, consequently, schemes of electrification are viewed from a financial standpoint. At present but little profit is being made because the cost of construction is necessarily high; there are heavy gradients, rather irregular traffic, short distances, high wages and low fares. Consequently the problem is not altogether simple. Nevertheless, there are certain cases in which operation by steam is almost prohibitive, as in the case of the Simplon tunnel or where the capabilities of steam locomotives are scarcely equal to the task imposed upon them, as in the case of the St. Gothard railway.

The more recent projects appear to be of great importance. Among these may be mentioned the Bern-Alpenbahn connecting Bern with the Simplon via the Lötschberg. This

Digitized by Google

is a new line, and it is important from the point of view of international traffic, as it will effect a considerable reduction in distance on certain routes to Italy. In many ways the conditions are similar to those of the St. Gothard railway, and for that reason the smoke from steam locomotives would be a disadvantage, and therefore electric traction has been favoured from the beginning. There are long gradients of 2·7 per cent. and the trains are heavy, requiring 2,000 H.P. or more. Single-phase traction has been adopted with a pressure of 15,000 volts and a frequency of 15. A short length of line from Spiez to Frutigen has been electrified, and this experiment has been so successful that the whole line is to be electrified on the same system. More than usual interest attaches to this line on account of the fact that two types of locomotive are being tried. In one of these, a 2,000 H.P. locomotive by the Oerlikon Company, power is transmitted by means of spiral gears which are automatically machine cut and run without noise or vibration, the surfaces in contact being much in excess of those of other types. The advantage, of course, is that reciprocating parts are avoided. The other type of locomotive is built by the A.E.G. It is of 1,600 H.P., with motors placed high in the cabin and with cranks on the motor shafts, from which motion is transmitted to the horizontal connecting rods of the driving wheels by means of intermediate connecting rods. It would seem that the geared locomotive will have a sphere of usefulness where speeds are low and a high draw-bar pull is required, whereas the reciprocating type can be used for higher speeds. Railway engineers will certainly watch the experiment with interest.

Another line which is to be electrified is that known as the Rhätische Bahn in the Engadin. Here again the single-phase system is to be used with a frequency of 15, but the pressure is only to be 10,000 volts, as it is a narrow-gauge line and the space in the tunnels is restricted. Finally, there is the projected electrification of the St. Gothard railway. This, of course, is a very important line, and is at present carrying as much traffic as can be handled by steam locomotives. There is any quantity of water-power along the route, and electric traction would no doubt be appreciated as giving more agreeable working in the tunnels and greater power in the locomotives, but the project is necessarily one that must be handled with the greatest care. The single-phase system at a pressure of 15,000 volts and a frequency of 15 is suggested.

A reference to the conditions in Switzerland would not be complete without some mention of the small commission initiated by Dr. E. TISSOT under the auspices of the Swiss Society of Electricians, and entitled Schweizerische Studienkommission für eletrischen Bahnbetrieb. This self-appointed commission, on which the railways, electricity works, manufacturing firms and technical science are all represented, appears to be doing extremely good work in facilitating the electrification of the railways. The object has been to investigate the merits of the several systems, the cost of plant and of operation, and to make a fair comparison between steam and electricity for definite railways. This has involved a great deal of work. The Commission has not stopped at such investigations, but has gone so far as to prepare complete schemes, such, for example, as that for the St. Gothard railway. Mr. HUBER-STOCKAR remarks that it is difficult to estimate the value of this work, but it is "certain that the collaboration in the Commission of representatives of interests in competition with each other in business has acted beneficially so as to make the question of system less one of competition and more one of general scientific and common practical interest." Certainly this seems to be an extremely good method of arriving at standardisation where such is possible, but perhaps it savours too much of combination to suit our insular minds.

REVIEWS.

Les Substances Isolantes et les Méthodes d'Isolement utilisées dans l'Industrie Electrique. By J. ESCARD. (Paris, 1911: Gauthier-Villars.) Pp. xx. + 314. 10fr.

A comprehensive work on insulating materials and methods of insulation, such as the book before us, ought to be welcome at the present time. No branch of electrical engineering needs or receives greater attention. Every installation is at every point dependent entirely upon the more or less satisfactory and permanent nature of the insulating materials employed. The qualities demanded of such materials, in addition to high specific resistance, are dielectric strength, surface insulation and mechanical properties such as strength, flexibility, ease of moulding or working; and it is necessary to know these qualities under all service conditions likely to arise and how they may vary with the lapse of time. These qualities are sufficiently various, and the materials to choose from may be more so. An experienced engineer will, therefore, be glad to have at hand a good work of reference on the subject.

Designers of electrical machinery in English-speaking countries are familiar with Turner and Hobart's useful work, and M. Escard should modify the statement in his preface that no work existed so far on the subject. The book before us, however, deals with all kinds of insulation, and only touches incidentally on the insulation problems of electrical machinery.

The opening chapters on electrical conduction and insulation in general are succeeded by sections in which are discussed the insulating properties, the dielectric strength and the surface and mechanical properties of all the materials of insulation: Air, natural minerals—such as mica, slate—porcelain, earthenware, rubber compounds, resins and varnishes and the numerous special insulating compositions; and finally oils and cotton and impregnated fibre materials. M. Escard succeeds in giving an attractive presentation of his subject from a scientific point of view and also from that of the engineer. Much of the book consists of a series of interesting essays with examples of observations illustrating the point under consideration, but frequently with no attempt to deduce technically useful figures on anything like a standard basis.

It would be very interesting, and we think it would greatly add to the usefulness of subsequent editions if the author would bring together in a table on a common basis, as far as it is possible, the essential qualities of every insulating material discussed—namely, specific resistance, dielectric strength, surface qualities and mechanical data, giving each at ordinary temperatures and also at, say, 50°C. higher. The book contains a great store of information from which such a table might be compiled.

Take, for example, the question of dielectric strength, whether of gaseous, liquid or solid insulators. Writers on this subject seem to have a tendency to forget that dielectric breakdown is caused by the maximum dielectric stress and not by average dielectric stress. In many places in the present work

Digitized by Google

one is quite unable, even roughly, to gauge the real stress to which the breakdown figures correspond. The form of the electrodes, the nature of the voltage, whether direct or alternating, and, if the latter, the wave form, are essential conditions which are rarely even stated, while of the resulting maximum stress no attempt at an estimate is given.

The book contains many excellent illustrations and curves of experimental results. With regard to the plotting of curves in engineering publications, most writers agree that the *cause* or independent variable should be laid off from left to right, and the *effect* or dependent variable should be plotted upwards. But in some writings such as the present book, this convention is ignored, and the curves given are entirely without system from this point of view.

Special attention is directed throughout the book to the high-tension aspect of insulation problems. With regard to surface insulation, reference is made to the observations of Mr. Highfield on the formation of nitrates on the surface of H.T. windings, a subject on which further information is wanted. The insulating properties of the air and how they are modified by ionisation under certain circumstances is a subject to which M. Escard directs considerable attention, and the earlier work of Prof. H. J. Ryan and Mr. Mershon (who appears as Merthon) is referred to. We trust that in a later edition the author will find time to incorporate the recent work of these and other engineers on losses off H.T. power lines, and also that of Mr. E. A. Watson on corona formation and the use of compressed air.

We hope that the reader of p. 67 will not expect rubber gloves to protect him against 120,000 volts, and we trust that no one will be led from p. 51 to try and measure the insulation reistance of cable samples without precautions against surface leakage.

A concluding reference should be made to the excellent collection of information which the book contains as to the composition and qualities of the large number of special insulating materials both solid and liquid which are sold under various trade names. It is not always too easy to obtain such information or to gauge the probable usefulness of any such substance for a particular purpose. D. K. MORRIS.

Electric Motors: Their Action, Control and Application. By F. B. CROCKER and M. ARENDT. (*London*: Crosby Lockwood & Son; New York: D. VAN NOSTRAND Co.) Pp. vi. + 292. 10s. 6d. net.

Of the great number of technical books published at the present day, very few rise above a certain level. It always affords pleasure to find a book of a higher standard and we only regret the present book does not hold a place among these few. The method of treatment, however, is quite original on the whole, and the value of the book is enhanced by the references to other books, papers, patents, &c. In fact, these are rather appalling, for at the end of each chapter there is a list of a dozen or so works to which reference can be made for further information.

First of all, the theory of the direct-current motor is simply explained in a way which will appeal to the man who only wants a superficial working knowledge, though, at the same time, there are several weak points. For example, the only method given of finding the temperature rise is by measuring the increase of resistance. This, of course, is an excellent method, but it cannot always be used, and some explanation should be given of the relation between the rise found in this way and that found by a thermometer. Further, although promises are held out that the armature reaction will be explained later, the explanation does not appear. This is very unfortunate, since armature reaction plays a far more important part in the working of a motor than is generally realised.

The methods of control are treated in a concise manner and the diagrams for series-parallel connections are very clear. We think, however, that the chapter on the method of varying the speed by altering the magnetic reluctance might well be omitted in a practical book.

Passing now to the second part, on alternating-current motors, we find these treated in a much more theoretical way, perhaps too much so for a book of this kind. The synchronous motor is dealt with first, then the polyphase induction motor and lastly the single-phase induction motor. The treatment of this last-mentioned machine is exceedingly academical, and in the space at the author's disposal it would perhaps have been better not to have gone into the theory so deeply.

The chapter on the alternating-current commutator motor is certainly not so good as the preceding, for in the limited space of 25 pages, it attempts to deal with the series, repulsion and compensated repulsion motors. Moreover, the authors do not appear to be quite up to date, since they tell us that these are only used on single-phase circuits, whereas a chapter on the speed regulation of three-phase induction motors by means of a commutator would have been a very useful addition.

The numerical examples given throughout the book are very useful and the figures and curves are full and clear. It is a pity, however, that in one or two places the lettering on the figures does not agree with the text referring to them. This is a point on which great stress should have been laid in correcting the proofs.

Extracts from the Standardisation Rules of the American Institute are added at the end, which should prove useful for reference.

On the whole, sufficient information is given, especially in the first part of the book, to impart a working knowledge of the subject but beyond this we cannot go. R. G. J.

HUNTING OF DIRECT CURRENT INTERPOLE MOTORS.

BY DR. E. ROSENBERG.

Summary.—The author discusses in detail the effect of brush currents on the field of a motor and shows that these may cause hunting to occur in interpole motors under certain conditions. Incidentally, the effects of the brush currents on the voltage regulation of generators and on the speed regulation of motors are discussed.

It is a well-known fact that in interpole motors hunting troubles may occur if the motor is working with a weak field, for instance, in motors for a wide range of speed which is

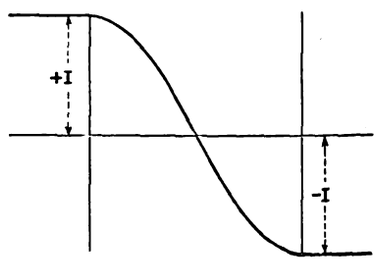

FIG. 1.

obtained by shunt regulation. This phenomenon has been discussed from time to time in the technical press, and in the "Elektrotechnische Zeitschrift," 1906, different explanations were offered by Messrs. Breslauer, Siebert, Pohl and others.

Dr. R. Pohl mentioned at the time that perhaps the hunting phenomenon may be explained by the short-circuit currents under the brushes. In this respect I fully agree with him, and I have tried in the following investigation to explain this influence fully.

In an interesting pamphlet, published some years ago, Pohl described the magnetic effects of the brush currents in d.c. armatures, mainly in machines without interpoles, and has pointed out the fact that in such machines the brush currents weaken the main field in generators, but strengthen the field in motors.

The fact can be easily explained. If the commutation was ideal, then the current of a coil passing a brush would gradually die down from its positive value +I to zero, for instance, according to a sine wave, and quite symmetrically grow again from zero value to the negative value −I (Fig. 1). The currents would then pass through zero in the geometrical centre

Digitized by Google

of the brush; therefore, if the brushes remain in the no-load neutral, the passing through zero would actually take place in the no-load neutral. It is, however, self-evident that without a commutating field such an ideal reversal of the current cannot take place. Due to self-induction, the current will surely, for some time, keep up the direction it had in the previous half revolution, and, therefore, the reversal will be delayed. The currents under the brushes will, therefore, virtually shift the line of armature reaction forward in the direction of rotation, no matter whether the machine is generating or motoring.

In Fig. 2 is shown the magnetic field and the distribution of current in the armature wires of a direct-current machine working as a generator and running in clockwise direction. The delayed reversal of current will take place in the line CD instead of in the no-load neutral AB. If we draw a line, EF. symmetrical to CD, then we see that the armature reaction of the armature portion between C and F, and D and E, gives an armature reaction at right angles to the original field, but that the zone between EC on the one side and FD on the other side gives a field directly opposite to the primary field. The first one is the cross magnetising armature reaction, the second a demagnetising one, although no brush shifting has taken place.

With exactly the same distribution of currents in the two halves of the armature, and with the same polarity of the field, the machine run as a motor with external current will, of course, reverse its direction of rotation. The self-induction of the short-circuited armature coils will naturally tend to keep up the old direction of current after passing the geometrical

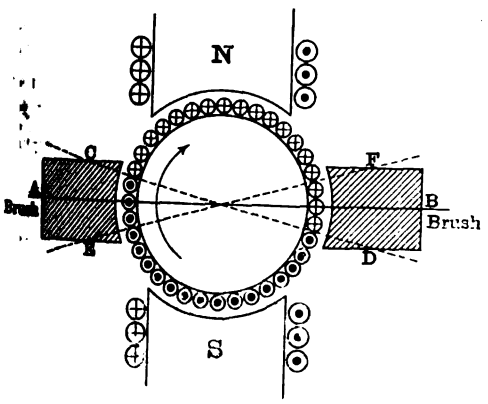

Fig. 2.—Distribution of Current in a Clockwise-running D.C. Generator.

neutral, and, therefore, the current in the zone A_1 to E_1 (Fig.) will be in the direction of the cross, the current from B_1 to in the direction of the point. The cross magnetising action f the armature is here just the same as in the generator, hereas the zone C_1 E_1 and D_1 F_1 has, as the figure shows, the fluence of strengthening the primary field of the motor.

So far we have considered only the effect of the armature self-duction on the delay of the current reversal. But a secondary fect of the armature reaction works in the same direction. ig. 4 shows in OI the direction of the lines of force of the ain field, and OII shows the direction of the field set up by amature reaction for the generator rotating clockwise. The me lines are shown for the motor rotating counter-clockwise Fig. 5. The field OII, working on the armature coils short rcuited under the brushes will produce an additional current hich has the same direction as the current had during the receding half revolution.

The magnetic influence of the short-circuit currents under ne brushes can be very considerable, and is, to a large degree, ependent upon speed, reactance of the short-circuited coils, idth of the brush and actual touching surface of the brush, nd, in consequence of the last-named item, also the mechanical ondition of the commutator is of great importance, and so it possible that high mica, a high bar, or a rough commutator urface influences the magnetic conditions of a machine to a onsiderable degree. It is not unusual that the ampere turns hich have to be added in a generator from no-load to full-load to compensate for armature reaction and demagnetising influences of the brush current are, in one machine, say, 10 per cent., and in another machine of exactly similar design, as high as 20 per cent.

In motors the magnetising action of the brush currents tends to reduce the speed with increasing load in the same way as the ohmic drop, whereas the field distortion caused by the cross magnetising ampere-turns counteracts this tendency. With a given brush position the armature reaction in two similar machines is exactly the same, and also the ohmic drop in armature windings and brushes varies very little in duplicate machines, but the influence of the brush currents varies to such an extent that it is not unusual to have in one motor a speed drop from no-load to full-load, say, of 6 per cent., and in a duplicate motor a speed drop of 10 per cent.

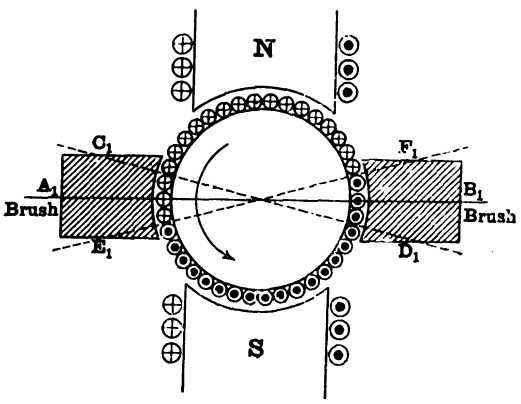

Fig. 3.—Distribution of Current in a Motor Running Counter Clockwise.

Being clear about the influence of brush currents in ordinary motors and generators without interpoles, we shall easily be able to understand the possible influence of commutating poles. A commutating pole of ideal proportions could produce an ideal commutation, as shown in Fig. 1, namely, a reversal of the current in the no-load neutral. If the commutating pole is too weak the reversal of the current will be delayed, therefore the action of the brush currents will be the same in quality, if not in quantity, as of a machine without commutating poles (Figs. 2 and 3). If the commutating pole, however, is too strong, the current reversal will take place before the no-load neutral is reached. In the case of a generator, therefore, the main field will be strengthened; in the case of a motor the main field will be weakened by the brush currents due to a strong commutating pole. The first thing explains the well-known fact that it is possible with proper brush position to obtain a level compound or over compound characteristic in a shunt machine with

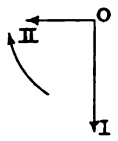

Fig. 4.—Magnetic Fields in a Clockwise-running Generator.

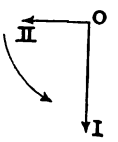

Fig. 5.—Magnetic Fields in a Motor Running Counter Clockwise.

commutating poles, even when fixing the brushes in the no-load neutral. Very often the compounding action is falsely attributed to the direct action of the commutating pole. This would offer an explanation, first of all, only for a brush position with a backward lead, for only then the commutating pole, having the polarity of the main pole following it in the direction of rotation, and being series excited, supports the main pole. Considering, however, that commutating poles are very often of such a small cross section that the total flux going through them is only a few per cent. of the main flux, and that a compound characteristic can be obtained even with brushes in the no-load neutral, it is clear that the direct action of the commutating pole is not a sufficient explanation, whereas the action of the

Digitized by Google

brush current ampere-turns working on the big magnetic mass of the main field explains the phenomenon fully.

With regard to motors, we repeat that the brush currents due to a commutating field which is too strong will weaken the main field. If the commutating pole was always too strong, and the brushes were in the no-load neutral, then such a motor would behave like a compound-wound motor with reversed series winding. If the current grows to such a value that the ampere turns of the series winding form a big percentage of the main ampere-turns, then serious trouble will occur as the motor has the tendency of speeding up with increased load. An increase in current will weaken the field, and, therefore, in order to give the torque required with reduced field the armature current will be further increased, reducing in its turn again the field strength, which at last might lead to racing of the motor and blowing of the fuses.

Now it is easily possible that a commutating pole with a given number of turns is too strong for small currents and too weak for big currents: also that it is too strong for low speeds and too weak for high speeds. Every designer knows that to give satisfactory commutation, say, at 100 per cent. overload, the ratio of commutating ampere turns to armature ampere turns has to be made bigger than in cases where the machine has only to deal with normal full load, and also that for high speed machines a bigger ratio is necessary than for low speed machines. Of course, if a machine commutates satisfactorily at high currents and high speeds, the commutation will, as a rule, still be satisfactory at low currents and low speeds, although the commutating field is then really stronger than necessary.

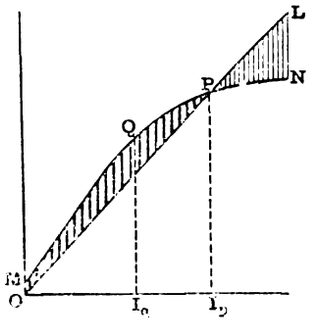

FIG. 6.

The change in the relative value of the commutating field will be particularly marked if the commutating pole has considerable leakage and has a small section. The magnetic characteristic of the commutating pole can be represented by the line MN in Fig. 6, the abscissæ representing the magnetising ampere turns, which are, of course, in direct proportion to the armature current I and the ordinates representing the field strength. The magnetisation curve will not start at the point O but at the point M, due to residual magnetism. The field set up in the direction of the commutating pole due to armature reaction and leakage can be represented as a curve OL, which is to all intents and purposes a straight line. This line cuts the curve MN, at a point P, corresponding to a certain armature current I_p, which, for well-designed machines, will lie sufficiently above the normal overloads with which the machine is expected to deal. In the above curve we have a positive commutating field for all currents below I_p, the corresponding vertical ordinates are represented by the thick shades in Fig. 6, whereas the thin shading in the part of the curve corresponding to armature currents above I_p shows negative values of the commutating field.

The critical point for the reversing of the magnetising action of the brush currents will, however, lie considerably below the armature current I_p, because we want a positive commutating field of sufficient strength to obtain the ideal reversal of the current in the centre of the brush. We may call the point corresponding to the ideal commutating field Q, in Fig. 6, the corresponding armature current I_q. For armature currents below the value I_q the commutating pole is too strong; for bigger armature currents the commutating pole is too weak. For lower currents, therefore, the main motor field is weakened, for higher currents strengthened.

Such an influence is well apt to set up hunting. In every motor, of course, slight oscillations of current occur all the time, due to the small oscillations of voltage in the impressed E.M.F., and due to small variations in the load torque, even if the motor is loaded with a practically constant load. In an ordinary motor, however, these oscillations work out their own salvation, because if the current is slightly smaller than that corresponding to the load torque this will cause a retardation, and the slight speed reduction will, in its turn, increase the current so as to be equal to that required by the load. In an interpole motor, however, as considered, if the current is for a moment smaller than it ought to be, the commutating field will be too strong and the brush currents will weaken the main field, thus causing the motor to speed up. With the reduced field the motor will take considerably more current, and the current might be so high that the commutating pole will then be too weak, which, in consequence of the brush currents, will strengthen the main field and will make the speed come down a very considerable amount, when the game starts fresh again.

The influence of the brush currents on the main field will, of course, be very marked if the field ampere turns are low, and that is the case at high speeds for a motor with field regulation. Suppose for a speed regulation of 1 to 4 the field ampere turns for the highest speed to be only 30 per cent. of the armature ampere turns, then it is quite clear that the brush ampere turns, even if only varying, say, between ±5 per cent., can make the motor unfit for use.

There are several remedies for hunting of interpole motors. One well known way is to increase the air-gap in the main field. It is clear that if, in the example given, the main field ampere turns at the highest speed are 50 per cent. of the armature ampere turns instead of 30 per cent., then brush currents of value of ±5 per cent. would have a smaller influence. In fact the brush currents would not even obtain this value, as the variation in brush current itself is reduced by reduced hunting and the cumulative effect is avoided. Therefore it often occurs that a small increase of the air-gap of the main field cures the trouble.

Another means is to rock the brushes forward in the direction of rotation. This has a double effect. First of all, the flux going through the commutating pole itself will now assist the main pole of the same polarity. Secondly, the brushes are no longer subjected to the full influence of the commutating pole. We know that by lessening the commutating field we lessen the demagnetising brush currents automatically. It is quite possible to bring, by this procedure, the brushes into such a weak field that the brush currents never weaken but always strengthen the main field. Anyhow, the actual shifting of the brushes by an angle α adds a number of magnetising ampere turns corresponding to the double angle 2α, and, therefore, demagnetising brush currents are set up they can be more than counteracted by these magnetising ampere turns, and by the assisting value of the commutating pole field.

This means, however, is only applicable in non-reversible motors, as, of course, the forward brush position for one direction would turn out a backward position for the other direction and aggravate the evil. For reversing motors the brushes have to be kept in the no-load neutral, and then it is important to keep the ratio between interpole ampere turns and armature ampere turns as low as ever compatible with good commutation. For this purpose the air-gap between interpole and armature should be made small, the pole tip should be shaped so as to give very small leakage, and the body of the interpole should have sufficient section so as to prevent saturation, and then it will be quite possible to commutate with a slight excess of interpole ampere turns. A well-designed machine is not so sensitive as to strike work if the commutating field is, say, 10 per cent. higher or lower than the best value, and here the negative margin should be used. Then only for very low currents the commutating field is slightly higher than the ideal value corresponding to these currents, but the demagnetising action is so small that it does not produce any appreciable

Digitized by Google

effect, especially considering that for such small armature currents the field distortion due to cross magnetisation is also negligible. For higher currents the commutating field will be on the low side. The brush currents, therefore, will not tend to decrease but even slightly to increase the main field, which tendency may partly be neutralised by the field distortion due to armature reaction.

There might be the objection that the commutation must be impared by keeping the commutating field on the low side. This would be true to a certain degree if we would consider only the stable conditions, but hunting impairs the commutation far more than an intentionally low value of the commutating ampere turns. For, as we have seen, when hunting begins the current may rise to such a value till the point is reached, anyhow, where the commutating field is too weak, for only this checks the further speeding up. But as we know that oscillations always necessarily go beyond the point of static equilibrium, the current in a hunting motor will increase considerably beyond this value, and the commutation, therefore, will surely be worse than if the commutating field from the beginning is weaker and does not give rise to hunting.

In some cases it might be sufficient to reduce the width of the brushes.

CORRESPONDENCE.

THE EDUCATION AND TRAINING OF ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to Dr. S. P. Smith's letter under the above heading in your current issue, and to your editorial notes on same, I beg to confirm what you say regarding the numbers of engineering students at the City and Guilds (Engineering) College, (late Central Technical College), South Kensington. As your figures show, the numbers taking the final year's courses must be reckoned by the hundred rather than by the dozen or half-dozen mentioned in Dr. Smith's communication. Dr. Smith also refers to the employment of technically trained men. Might I be allowed to say that the "enlightened employer" is not quite such a "rara avis" as Dr. Smith supposes. There has been a distinct move in the right direction during recent years, and several progressive firms now make a practice of applying some months before the end of our session for names of men we can recommend for employment. One such firm has taken seven of our men this month. This feature has become most marked in electrical engineering, and for the past two years my chief difficulty has been, not to find posts for our men, but to find men for the posts offered. In fact, the demand has exceeded the supply.

It is to be hoped that this satisfactory state of affairs will continue, for in addition to showing that the services of technically trained men are being more appreciated, it is also indicative of revival of business in electrical circles.

South Kensington, July 31. T. MATHER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I regret I did not make sufficiently clear in my letter of the 20th inst. what I meant by "departments of engineering." In most colleges, engineering is usually taught in several departments, such as civil, mechanical, electrical, mining, metallurgy, naval architecture, and it was these departments I had in mind when I mentioned that "in many of the departments scarcely a dozen students reach the course in the final year, and in many colleges this number would have to be halved."

This statement, strange though it may seem, you will find amply borne out from the examination lists published in the calendars of the provincial universities in this country; indeed, in several cases, the *total* number of engineering students, in the degree course, *successful* in their final year is below twelve.—I am, &c.,

Birmingham, July 31, STANLEY PARKER SMITH.

THE PRESENT STATUS OF OZONE WITH REFERENCE TO AIR PURIFICATION.*

BY R. D. SMALL.

The development of ozone for industrial uses, water purification and ventilation has progressed rapidly since 1903, a date which seems to be the median line between inaccuracy and accuracy, so far as determination, concentration, economical operation, properties and uses of ozone are concerned. In 1890, the French Academy of Sciences appointed a commission to report on the status of ozone in Europe. After a lengthy investigation, their report submitted proved absolutely inconclusive. The members were almost divided as to what they recognised had been scientifically proved. From 1895 to the present date the whole subject has been largely taken out of the laboratory and put on a commercial plane, and this has been chiefly dependent upon the progress and developments that have taken place in the electrical industry.

For air purification purposes, to a consideration of which this Paper is devoted, ozone is now being made with generators, which first change the direct current to an alternating current, preferably with a frequency of not less than 60, and then step-up the voltage to from 5,000 to 30,000, although it is now thought that to obtain the best economies, a voltage under 8,000 is poor practice. The discharge is made by electrodes on either side of a dielectric, such as glass, micanite, mica or some high insulating material, there being an air-gap between the dielectric and the electrodes. The electric glow, which has no sparks such as are exhibited in the voltaic arc, and which is comparatively heatless, is a brush discharge, purple in colour and fairly quiet in its action. Various types of condensers and electrodes have been used from 1859 down to date. The consensus of modern opinion is that point electrodes, such as employed by Andreoli and others, have disadvantages; first, because they quickly lose their pointed character and round off, or, second, because a minute particle of dust can do a great amount of destructive work on a small point in generating heat and interrupting the flow of electricity; third, because the necessary cleaning of an infinitely large number of points requires too much attention. Leon Gerard, one of the leading electrical engineers of Belgium, states: "The aigrette or point electrodes apparatus has only 55 per cent. efficiency of those where the glow discharge is used." Other types of electrodes are either plates or cylinders on either side of a dielectric material, and these appear in various forms—flat, serrated, gridded or perforated. Another type is the covered electrode, with no metal exposed, which is very commendable. A fourth in use is a rotating fan electrode, such as is shown in the Vohr type, which has the advantage of quickly forcing the air through the generating field and ozonising it at the same time, thus giving a high purity of product. It is generally regarded as axiomatic that the briefer the period of ozonisation, the purer the resultant gas, purity meaning practically an absence of oxides of nitrogen, which are principally produced by heat, sparking or the presence of dirt. The amount of nitrous oxide generated by any properly made type of air ozoniser, however, is so infinitely small that it can be totally disregarded. This statement, however, does not apply to all ozonisers, as will be later explained. It may be stated that the more modern machines consume in operation 40 to 250 watts per hour.

Of all known subjects which are intimately connected with our health and working efficiency, the least understood, the least attended to, with the most widely varying opinions in regard to it, is the subject of air purification and the chemistry of the air we breathe. What is the harmful part of bad air? The consensus of modern chemists, physicists and scientists on this subject is absolutely conclusive; it permits of no debate. Experiments have been tried, tests have been made, and the old bugaboo—carbon dioxide—has been effectually exposed. Many persons used to entertain an idea which is rapidly becoming obsolete, that is, that the carbon dioxide in the air is the particular thing that creates the harm. Carbon dioxide is harmful only in that it reduces the oxygen supply by displacing it. As long as you can get the proper percentage of oxygen in the air that you breathe, the amount of carbon dioxide produced in any chemical laboratory can be present, according to the best scientists of the last 10 years, to an amount of 20 times that which many engineers put as a figure destructive to life. Carbon dioxide is not poisonous, but when present in quantities in any air it is a danger sign that impurities exist in that air. It is a signboard, and not the danger itself. It is the organic impurities exhaled at the same time as the carbon dioxide that are poisonous, so merely getting rid of carbon dioxide is a good deal like burning up the danger sign to get rid of the danger.

* Abstract of a Paper read before the American Electrochemical Society.

Digitized by Google

Organic impurities come from a variety of sources, as has been previously mentioned. In all confined spaces, however, the chief source of air pollution is the organic matter cast off through the pores of the skin and the nose, throat and mouths of the individuals occupying that space. The longer that matter which the body has cast off remains suspended in the air, the quicker it deteriorates. When it reaches a putrescent state, it is unfit to be re-breathed. This air is sewage, and is just as unfit to take into the system as diseased meat would be unfit for the stomach. What our body has cast off it is safe to assume is unfit for further use. This organic impurity has recently been called "crowd poison," according to Dr. Fischer, in "Ozone and Air Purification." He states: "What is known as 'crowd poison' is responsible for many of the bad air diseases. A large amount of decomposition is continually going on upon the surface of the body and in the nose, mouth and throat of every individual, so that large quantities of these 'decomposing products' are thrown out into the air. As these substances are formed more rapidly when there are a number of persons confined to the same space, they have been called 'crowd poisons.' Wherever there is decay, there is bound to be odour, and the unpleasant smell in confined spaces is due to this 'crowd poison.'

So that it would seem that, while ventilation is necessary to bring in out-of-door air to replace the oxygen which our breathing uses up, outdoor air alone is absolutely insufficient to purify the indoor air. It never did and never will destroy the impurities that constitute the danger element. Nature purifies her atmosphere with ozone. Man can purify it only with ozone. Nothing has been said about ozone as a deodoriser. Its properties are remarkable in this line, and with higher concentrations, almost any odour known—excepting the extraordinary perfumery from the pole-cat—can be successfully combatted. In an office, factory or home, the chief odours to be eliminated come from tobacco smoke, cooking, laundry, sick-rooms or any overcrowded spaces.

It now seems to be regarded as an accepted opinion that colds and kindred diseases come from bad air, chiefly because bad air disturbs that part of the nervous system which regulates the blood circulation, and local blood congestion ensues, bringing with it an interference with certain bodily functions which destroy the bacteria constantly taken into the system. Thus infection occurs, lowering resistance to disease, and we start with colds, which are frequently the forerunners of tonsilitis, bronchitis, pneumonia, and even tuberculosis. Undoubtedly ozonised air acts as a preventative of conditions which bring about many of our colds, and it is on the preventative rather than on the curative side that it has a serious claim to consideration. Pure air will help the body to cure itself, and that is all that ozonised air in a concentration proper for breathing will do; but interrupted administrations of ozone in high concentrations certainly cannot be seriously considered as beneficial as its continued use in more diluted and diffused form.

The use of ozone in the purification of air is undoubtedly one of the most valuable of the newer achievements of electrochemistry, first, as a preventative of conditions which undermine health; second, as a promoter of working efficiency, which involves the third—an increase of business output, so that commercial and physical welfare are materially aided by a little boxed-up lightning placed in one's office, factory or home.

LONDON COUNTY COUNCIL TRAMWAYS.

On Tuesday the Highways Committee of the London County Council submitted the accounts of the tramway undertakings for the year ended March 31.

The accounts have been approved by the Finance Committee. The tramways system on March 31, 1911, extended over a total length of 143⅔ street miles, 126¼ miles of electric and 17⅓ miles of horse lines. The whole of the system is worked by the Council with the exception of 2¾ miles (partly double and partly single line) of track in Harrow-road and ⅜ mile (double line) in Archway-road, Highgate, which are worked by the Metropolitan Electric Tramways. The capital expenditure on the undertaking up to March 31 was £11,618,836. 17s. 7d., of which £909,333. 1s. 9d. represents expenditure during 1910-11. The total sum provided for redemption of debt amounted to £1,710,162. 19s. out of revenue, and £328,716. 4s. 3d. from proceeds of sales of horses, old materials, &c. The net debt, after deducting £114,458 in respect of value of surplus land was, therefore, £9,465,499. 14s. 4d. The Council decided on June 23, 1908, subject to the approval of the Treasury, to repay the outstanding debt (estimated at £960,000) on the capital which will be obsolete on March 31, 1914, owing to the electrification of horse tramways, within 15 years from that date. The amount of obsolete capital on March 31, 1911, was £1,750,905. 1s. 6d. Deducting amount provided out of revenue and from sales of horses, &c. (£738,905. 4s. 4d.), the amount still to be provided for in respect of capital already obsolete is £1,011,999. 17s. 2d. The total income from the undertaking during the year and the working expenses were as follows:—

	Electric traction.	Horse traction.	Total.
Income	£2,150,239 12 9	£82,578 3 1	£2,232,817 15 10
Working expenses	1,235,821 13 11	101,947 19 2	1,337,769 13 1
Surplus on working	£914,417 18 10	£19,369 16 1*	£895,048 2 9

Interest amounted to £319,165. 12s. 11d. and redemption fund to £337,825. 8s. 2d., and after paying income tax and other charges there was a surplus of £232,727. The Council decided on June 23, 1908, that provision should be made for renewals at the rate of ¾d. for each car-mile on the total car-mileage run on the electric tramways each year, and that the question of the adequacy or otherwise of this provision should be again considered at the expiration of five years. Provision for 1910-11 at this rate, amounting to £127,281. 5s. 2d., has been made. £1,947. 9s. 11d. has also been provided in respect of the lines in Harrow-road leased to the Metropolitan Electric Tramways, making the total sum transferred from appropriation account to renewals fund £129,228. 15s. 1d. The renewals fund on March 31, 1911, amounted to £527,263. 17s. 6d. The Council also decided on June 23, 1908, on the recommendation of the Finance Committee, that a general reserve fund to provide for general contingencies, should be established, to which any balance remaining, after providing fully for renewals, should be carried, and in accordance with this decision £103,497. 19s. 4d. has been transferred from appropriation account to general reserve compared with £59,878. 8s. last year. The reserve fund amounted to £176,844. 18s. 5d. on March 31, 1911.

The total operating expenses for electric traction system were £1,235,821. 13s. 11d., including £22,993. 5s. 4d. for special charges, or 6·48d. a car-mile run, compared with 6·42d. in 1909-10. The total working expenses in connection with horse traction amounted to £101,947. 19s. 2d., or 10·38d. a car-mile run. Passenger traffic receipts in respect of electric traction amounted to £2,096,913. 16s. 7d., or 11·00d. a car-mile run, compared with 11·21d. From lines operated by horse traction the traffic receipts amounted to £80,580. 0s. 9d., or 8·20d. a car-mile run, compared with 8·14d. In considering the decrease of 0·21d. a car-mile as regards electric traction, the Committee remind the Council that, as stated on May 23, 1911, in their report with regard to tramways estimates for 1911-12, the receipts per car-mile are not necessarily an accurate index of the prosperity of the undertaking. It has been found in regard to a number of routes to be financially advantageous to increase the mileage run within certain limits; for instance 120 car-miles run with receipts at 10½d. a car-mile give a more satisfactory result than 100 car-miles with receipts at 11d. a car-mile. The surplus on working, assuming the working expenses per car-mile remain the same, would be greater while the debt charges would be increased to only a slight extent. In connection with the decrease a car-mile it must also be borne in mind that the most remunerative routes were the first to be reconstructed. During the past year less remunerative lines have been electrified; moreover, the weather during the summer and autumn of 1910 was wet and cold, while the increasing number of workmen carried each year contributes to the falling off in the receipts a car-mile run. Considerable loss was sustained during the reconstruction of horse lines for electric traction, as sections of some of the routes had to be closed, and this disorganised the traffic on several important routes. The lines opened during the year include the new tramways in Farringdon-road, Lea Bridge-road, from Woolwich to Eltham, in Mitcham-lane, Southcroft-road, Wimbledon-road, and from Brockley to Forest Hill, and the re-constructed tramways in Lea Bridge-road (from Cornthwaite-road to the county boundary at Lea Bridge) and from Tooley-street to Rotherhithe New-road. The total number of passengers carried and car-miles run during the year were as follows:—

	Electric traction.	Horse traction.	Total.
Number of passengers	482,296,935 ...	22,418,391 ...	504,715,326
Number of car-miles run ...	45,744,066 ...	2,357,504 ...	48,101,570

* Deficiency.

PARLIAMENTARY INTELLIGENCE.

ROTHERHAM CORPORATION BILL.

Before Lord Lamington's House of Lords Committee on Thursday last Mr. Honoratus Lloyd, K.C. (for the Great Central Railway Co.) said the company would be hit if the Corporation's tramway, trackless trolley and motor 'bus proposals were not a financial success. Bradford and Leeds were running trackless trolley cars inside their own borders, but power to run them in outside districts should not be granted.

On Friday Mr. STEPHEN SELLON gave evidence in opposition to the scheme. In his opinion it could not be a commercial success. The average of the proposed fares and the estimates of the number of passengers were too high.

Mr. TALBOT, K.C., for the Midland Railway Co., said the very Committee before which that Bill was brought in the House below and which, through some inadvertence, had allowed the Bill to go through without hearing the opposition, laid it down in the Newcastle case that unless they had the consent of the outside authorities they could not sanction the installation of rail-less traction outside borough boundaries.

Mr. RAM, K.C. (for the Corporation) said the tramways had been so successfully administered that the opposing companies, as ratepayers,

Digitized by Google

had received substantial remissions of rates. The Midland Railway Co. had received £870 in five years and the Great Central £1,263.

After the Committee had deliberated in private, the Chairman said the decision of the Committee was that the Bill might proceed on condition that in respect to the trackless trolley undertaking it was necessary that the whole of the equipment authorised should be completed by Jan. 1, 1914, so far as outside borough limits were concerned; that the railways opposing the scheme should come under the district rates in respect of that system so far as it was outside the borough limits; and that the Corporation should put in a depreciation clause to satisfy the Board of Trade in respect to the undertakings authorised by the Bill. Those conditions also applied to the motor-omnibus routes.

ABERDARE URBAN DISTRICT COUNCIL'S BILL.

Consideration of this Bill was commenced by a Select Committee of the House of Commons, presided over by Sir Luke White, last week.

Mr. WEDDERBURN, K.C. (for the Council) said practically the only part of the Bill that was opposed was that relating to tramways. They had made three applications for powers for tramways but had failed on technical grounds. He had technical witnesses who would tell the Committee that trams could be run in Aberdare at a fair profit, so that the only argument that remained to the Taff Vale Railway Co., who opposed the Bill, was that of competition. The County Council said the rail-less cars would wear and tear the route, but the House of Lords had dealt with that and said the Urban Council were to contribute one-third of the cost.

Mr. STEPHEN NELLON and others gave evidence in support of the Bill.

Mr. BEASLEY (general manager of the Taff Vale Railway Co.) said 75 per cent. of their passengers might use the tramways instead of the railway.

The CHAIRMAN: From one aspect you say there will be a loss to you as ratepayers and from another you say that these tramways would be so convenient for the public that they would take 75 per cent. of your customers?—That is our point. We shall be contributing to a scheme that will be depriving us of custom.

The CHAIRMAN subsequently announced that he did not think it necessary that the Committee should hear Mr. Wedderburn, K.C., for the promoters as the Committee were unanimously of opinion that the preamble of the Bill should be passed.

Mr. TALBOT objected to a clause which provided that the limitation in the weight of parcels which the trams would carry should not apply to a number of small parcels together, but the Committee allowed the clause as it stood.

TELEGRAPH (CONSTRUCTION) BILL.

This Bill has been further considered by a Hybrid Committee of the House of Commons, of which the Postmaster-General was chairman, and on Tuesday they gave their decison as to the opposition of the Caledonian and the Glasgow and South-Western Railway Companies. The object of the Bill is to authorise the Postmaster-General to carry telegraph wires where they run along the public roads, "across" railways without having to seek the consent of the railway companies. 10s. per mile of wire is now paid by the Post Office in consideration of the companies waiving the right of maintenance under agreement. The prospect of the acquisition of the telephones by the Government raised the question of the continuance of a fee of £1 per mile at present paid by the company for the right of "cross." The Government would only pay 10s., which in the case of the Caledonian Co. meant a reduction of an income of £3,600 a year by one-half. But under the Bill even that payment will be altogether extinguished, as the Post Office will acquire the right of maintenance.

The POSTMASTER-GENERAL said the Committee had come to the conclusion that the case of the two railway companies had not been established, and that they would report the Bill without the recommendation of any amendment except those which had been agreed to. He was thankful to say, after consultation with the authorities of the House and consideration of the precedents, that there was no objection to the Postmaster-General being in the chair of a Hybrid Committee, even when his own department was concerned. The decision of the Committee would have been the same had he not been in the chair.

AUTOMATIC TELEPHONES.

In the House of Commons on Tuesday Mr. V. Kennedy asked the Postmaster-General if he intended to introduce into England the Strowger and Lorimer automatic telephone systems: what had been the cost to date in connection with the experiment: and what amount was it calculated it would cost to continue the same for, say, six months.

In reply, Mr. SAMUEL said that contracts were in course of arrangement for two experimental exchanges to be constructed at Epsom and Caterham Valley on the Strowger and Lorimer systems respectively. No special expense had at present been incurred for the purpose, nor could he say at what cost would be involved in working and maintaining those exchanges. The determination of the cost was one of the chief objects of the experiment.

Greater London Railway Bill.—A Committee of the House of Lords has during the week been considering this Bill, which has already passed the Commons. Yesterday (Thursday) the Committee found the preamble not proved.

Naval Wireless Telegraphists.—In the House of Commons on Monday Mr. McKenna said, in reply to Mr. Remnant, the discharge by purchase of telegraphist ratings is not prohibited altogether, but orders are in force that all applications for such discharge shall be carefully scrutinised and allowed only in really urgent cases. With the growing requirements of wireless telegraphy in the Fleet, it is desirable that the expansion of this new branch of the naval service shall not be checked more than is necessary.

Newcastle Corporation Bill.—On Wednesday a Select Committee of the House of Lords passed the tramway clauses of this Bill, but the carrying of goods and minerals is to be prohibited if the N.E. Rly. Co. desire. The clause inserted in the Rotherham Bill, which provides that in outside areas the railway company should be assessed on only one-fourth of the annual net value of any property which they hold for making good any loss made upon the tramways in question, was also inserted.

Brighton, Hove & District Rail-less Traction Bill.—On Wednesday this Bill, which had already passed the House of Lords, was considered by a House of Commons Committee. After hearing evidence, the Committee passed the Bill, and required the completion of the work of construction within two years.

LEGAL INTELLIGENCE.

Taxation of Municipal Undertakings.

On Saturday in the Court of Appeal the Master of the Rolls and Lords Justices Farwell and Kennedy heard an appeal by Leeds Corporation against a judgment of Mr. Justice Hamilton affirming an assessment on certain Corporation undertakings, including waterworks, gas, electric lighting, markets and tramways. The Income Tax Commissioners sought to make the Corporation liable to assessment on the profits of each separate undertaking, but the Corporation claimed that as, under their special Acts, they had pooled the profits for the purpose of meeting the interests on the loans applying to the undertakings, and as the tax had been deducted in respect of the interest, they were liable only for the balance which they had to raise by rates.

The MASTER of the ROLLS said that the question was whether the Corporation could apply the profits arising from one municipal undertaking to the payment of interest on loans for another. The Corporation by their Acts had raised large loans on the security of either the City Fund or the Consolidated Fund, and in no instance did the security extend to both funds. The interest on the loans was no longer payable out of the net receipts of one or other of the undertakings, but out of the common dividend fund which they had created under their Act of 1901, and in his opinion the decision of Mr. Justice Hamilton could not be supported, The appeal would therefore be allowed.

Lord Justice FARWELL said the Crown's contention amounted to payment of income tax twice over.

Lord Justice KENNEDY dissented, and thought the appeal should be dismissed.

By a majority of the Court the appeal was allowed and the order of the Court below was reversed, with costs.

Thermal Synd. (Ltd.) v. Silicaware (Ltd.)

On Monday Mr. Justice Swinfen Eady delivered judgment in this case. His lordship said the action was brought to restrain an alleged infringement of letters patent granted to J. F. Bottomley and Arthur Paget for improvements connected with the working of silica. The patent disclosed a process for working silica whereby it could be rendered plastic and could in that condition be removed from the furnace and then drawn or blown into any desired shape. Hitherto great difficulty had been experienced in the working of silica for commercial use, chiefly from the generation of gases in the furnace. His lordship reviewed the efforts prior to plaintiffs' invention, in which the oxy-hydrogen flame and the electric arc furnace were used. So far from being troubled by the gas generation, plaintiffs' invention actually took advantage of it. A graphite rod was fixed between two electrodes and covered with glass-makers' sand. A current of 15 kw. was then passed through for half an hour, and fusion took place at a temperature of 1,800°C. The great utility of such an invention was beyond question, but defendants disputed its validity and denied infringement. Defendants imported and sold in England articles made abroad from silica; the articles complained of by plaintiffs were said to be made on the Rhine. He had had great difficulty in ascertaining the actual process used in the manufacture of defendants' articles, but it appeared that they were made by semi-fused silica. Defendants denied that their process made use of the pressure of internal gas in the same way as plaintiffs'. It was clear from the evidence that plaintiffs' process, as described in their specification, was sufficient to achieve the purpose desired, whilst, on the other hand, the evidence of defendants in regard to their exhibits was extremely unsatisfactory and unreliable. He was of opinion that the articles complained of were made by a process the same, or substantially the same, as that of plaintiffs' invention, and the separation of fused silica at the core was obtained by gas pressure. In his judgment, plaintiffs' patent was a valid one, and defendants had infringed it. He would grant the injunction asked for, with costs, an enquiry as to damage, and a certificate of validity. He also made an order for immediate delivery up, on terms that plaintiffs undertook, in case of appeal, not to dispose of the articles so delivered up, or, in the alternative, an order for destruction.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Acton.—At the last meeting of the council, Coun. Page moved to rescind the resolution to use gas for lighting the Acton Park bandstand and to accept the offer of the Metropolitan Electric Supply Co. The motion was carried by 4 votes to 3.

Barking.—Messrs. Robt. Hammond & Son, who were recently engaged to report upon the proposed extension of the electricity undertaking at a fee of 50 guineas, have now presented their report.

Belfast.—The Corporation have applied to the L.G. Board for sanction to a loan of £40,000 for extensions of plant, cables, &c.

Bingley.—The Council have adjourned discussion of the request of the Electrical Distribution of Yorkshire (Ltd.) for assent to an application for a provisional electric lighting order for Bingley. Inquiries are being made as to the possibility of obtaining supply from Bradford, Shipley or Keighley.

Bolton.—The Council have applied for sanction to a loan of £20,000 for mains extensions, &c.

Braunton (Devon).—The arrangements for the formation of the Braunton Electric Light & Power Co. (Ltd.) are said to have been completed and that a supply of current will be available by the end of the year. Mr. Alan Jenkins, of Ilfracombe, drew up the scheme, and Messrs. Crompton & Co. will carry it out.

Chartered Institute of Patent Agents.—The qualifying examination of persons desirous of being registered as patent agents will be held in November next. A notice giving particulars appeared in the "Illustrated Official Journal (Patents)" of July 5, and a copy of the notice can be obtained from the Secretary, Chartered Institute of Patent Agents, Staple Inn-buildings, London, W.C.

Edinburgh Art College.—Edinburgh Council have approved the Electric Lighting Committee's recommendation that out of the surplus of £8,431 on the past year's working of the electric lighting undertaking such sum as may be necessary to meet one half the remaining sum required for the building of the Art College shall be devoted to that purpose, on condition that the other half is met by the Government.

Electric Cooking, &c.—Mr. F. S. Grogan (of the Berry Construction Co.) gave demonstrations of electric cooking at the showroom of the National Electric Supply Co., Preston, last week.

The "Tricity" cooker was used in the demonstrations and it is stated that a 10 lb. joint can be cooked for 2½d., and that the loss of 1¼ lb. of meat, which would take place by any other method, is avoided. A pint of hot water can be obtained in 3½ minutes. "Tricity" laundry irons were also shown to be quick and effective.

Electric Lifts in Infirmaries.—Croydon Guardians last week adopted a recommendation to proceed with the electrification of two of the lifts at the infirmary and Mr. A. C. Cramb, the borough electrical engineer, was asked to prepare a specification. Mr. Cramb had advised the adoption of electric power and the approximate cost would be £210 per lift, or £250 per lift including accessories and structural alterations.

Electricity in Mines.—At the Miners' International Congress in London last week, in proposing a resolution calling upon the Governments of the different nations represented at the Congress to proceed at once with such legislation as will tend to greater safety for the mine workers, Mr. Albert Stanley, M.P., returned to his attack on electrical working in mines and said:

There are three leading amendments upon which the representatives of the miners would insist. The first would be to secure better ingress to and egress from the mines, the second for a better system of ventilation; and the third with regard to "that new, weird and intangible, but very terrible, factor, the employment of electricity in mines." Electricity was (he proceeded to tell his awe-struck audience) a strange and mysterious thing in itself, but when supplemented by the other dangers of coal mines "it became a very terrible thing indeed." He said he was supported by the best technical opinion in Great Britain (which he entirely forgot to disclose) in the view that one, if not two, of the most appalling mining accidents in recent years were due to explosives caused by sparks given off by electrical apparatus. In the disaster in the West Stanley mine every possible factor except electricity had been eliminated, and he believed that Mr. Redmayne, the Chief Inspector of Mines, held the opinion that the explosion was due to electricity. [Mr. Redmayne has nowhere to our knowledge made such a statement.] One of the greatest electrical experts in England had located the centre of the explosion at a switch-box. When they saw electrical coal-cutting machines fusing not only the cables carrying the current but the rails on the ground, it was idle to talk of the danger from candles or defective lamps in comparison with the risk from "this new and terrible agent."

Electricity in Kent Collieries.—At the meeting of the South-Eastern Coalfield Extension (Ltd.) last week, the director-general (Mr. Arthur Burr) referred to the electrical plant which the company was having installed.

He said he was a little bit prejudiced at first, because of the failure of the electricity works under the Shakespeare cliff, but when he made inquiries he found that any colliery that was being constructed or opened up without the use of electricity was quite out of date; most of the modern collieries were not only pumped electrically but they used electricity for all motive power, and some—the most modern—actually used it for their winding engines. Electricity did not cost anything like so much as steam. Their engineer told him it would be of greater benefit than steam. Mr. Metzger was appointed their electrical consultant, and he received instructions to order their electrical plant. A schedule of what was ordered could be seen by any shareholder. The total cost of the contracts was about £30,000 of which he had paid £15,000 already. Mr. Hamilton, who had relieved him of the position of managing director of the East Kent Colliery Co., and Mr. Hallingsworth were asked to prepare a memorandum as to what they thought of the situation.

In his statement Mr. Hamilton said the progress made at Tilmanstone was entirely to his satisfaction and beyond their expectations. The installation would fully answer all requirements.

Mr. Metzger reported that the power station at Tilmanstone would enable them to use electric power at Snowdown. They would get the Royal assent in August to their Bill, which would give them control of the whole of the electric power stations in that part of England.

Electricity Meter Testing.—The Manchester Justices' Committee who are in charge of the Gas Meter Testing Department of Manchester, have prepared a special report for submission to the city justices.

The committee say that, following the suggestion made by the Lord Mayor on April 28 that the testing of electricity meters should be placed under them, it was considered desirable that information should be obtained regarding the present practice of testing in Manchester. To this end the chairman (Mr. Nathaniel Bradley) met the chairman of the Electricity Committee (Mr. Howarth) on June 29. The point urged by Mr. Bradley was that, although there was no Act of Parliament to regulate the testing and sealing of electricity meters, it was desirable that the meters should be tested and sealed by an authority other than the sellers of the electricity. The report of the deputation from the committee, who visited several gas-meter testing stations in July, 1906, contains a paragraph referring to the London County Council electricity meter testing offices, which reads: "Amongst consumers of electricity and water there is a growing feeling that, their case being analogous to that of gas consumers, there *ought* to be established some independent authority for testing the apparatus of measurement similar to that provided by the Justices' Committee under the Sale of Gas Act, 1859, for testing gas meters. Naturally the feeling is particularly strong amongst the users of electricity for lighting purposes, as they notice the absence in the meter for the new illuminant of that independent testimony to accuracy which is given by the seal of the testing station in the case of gas meters; and your committee are of opinion that it should be made compulsory for the sellers of electricity or water to supply meters which have been tested and sealed by an independent authority." The committee go on to say "Some towns being producers of electricity have instituted test stations under their own control. This is the case in Manchester. There is no doubt of the desirability of an independent testing authority for Manchester, but in the absence of statutory powers the work could only be transferred by the consent of the Manchester Corporation."

The Justices met on Monday, when Mr. Bradley moved the adoption of the Committee's report abstracted above.

Mr. GEO. HOWARTH (Chairman of the Electricity Committee) said the electricity authority had rather prided themselves on the way the work of electricity meter testing was being done. They had had no complaints as to the accuracy of the meters or other instruments. The justices had no power to enforce what they proposed.

Col. CROOK said the gas meters were tested by a separate authority. It paid the Corporation to have correct meters, for he understood that as a rule, the inaccuracy was generally against the Corporation.

The report was received and referred to a committee composed of representatives of the Justices and of the Electricity Committee.

Fatality.—Mr. Sidney Douglas, an assistant mains engineer of the Lancashire Electric Power Co., was accidentally killed on Saturday afternoon at the Swinton and Pendlebury sub-station. Deceased was investigating a fault, when by some means he came in contact with the machinery, and died a few minutes later.

Digitized by Google

Glasgow.—A deputation of Glasgow Councillors and officials of the Tramway Department is visiting the works of various makers of turbo-generators in England and on the Continent with a view to advising the Tramways Committee with regard to the turbo-generators to be installed at Pinkston power station.

Goole.—Electrical Distribution of Yorkshire (Ltd.) propose to apply for a provisional electric lighting order for this district.

Hammersmith (London).—The Council decided last week to set aside £300 from the revenue of the electricity undertaking for advertising, including the salary of the present canvasser (£156).

Haslingden.—The Corporation have obtained sanction to borrow £8,188 for electricity supply purposes. Current in bulk will be taken from Accrington Corporation, with whom a seven years' agreement has been entered into.

Heston and Isleworth.—The Council have decided to reduce the price of current to free-wired premises from 5½d. to 5d. per unit.

Hospital Lighting.—At the meeting of the Salisbury and District Joint Isolation Hospital last week the architect, Mr. J. H. Goodman, dwelt upon respective merits of air gas and electricity as illuminants. In view of the disadvantages and failures experienced in connection with air gas he recommended the electric light as more economical in the end. It was resolved that electric lighting be adopted, and the architect was instructed to obtain tenders.

Hoyland (Yorks.).—The Council have decided to engage an expert to report on the advisability of carrying out an electric lighting scheme and to give an estimate of the cost.

Inquest.—An inquest was held at Rugby on Friday into the circumstances attending the death at the British Thomson-Houston Co.'s works on July 26 of Harold R. Fisher, who was employed in the testing department.

Mr. J. M. Ralph, chief of the department, said on Wednesday morning a test was being made of a motor generator, and deceased was connecting the terminals when the accident occurred. The test was of an ordinary kind, but the connections had never been used in exactly the same manner as on this occasion. It appeared that some copper strip had been connected up with the turbine as well as with the generator, and this fact was not known to deceased and others engaged on the work. The current in the circuit with which deceased came in contact had a pressure of 2,100 volts. A verdict of accidental death was returned.

Institute of Chemistry.—The pass list for the June-July examinations, 1911, at the examinations held in London and Glasgow, show that of the 31 candidates for the intermediate examination 17 were successful:—

Messrs. J. L. S. Allan, K. C. G. Arbuthnot, B.A., R. Clark, T. W. Dermott, E. C. Evans, B.Sc., H. Gilmour, R. E. Griffiths, B.Sc., C. L. Hayes, R. P. Keith, J. G. King, R. Linch, B. B. Murdoch, M.A., B.Sc., L. J. Robb, B.Sc., J. W. Tait, M.A., F. G. Tarn, T. A. Wilson, F. G. C. Yaker.

Of 34 candidates for the final examination for the Associateship, 23 passed. In the branch of Mineral Chemistry: G. Hamilton, S. R. Illingworth, A.R.C.S., E. A. Masters, B.Sc., C. B. Roos, B.Sc., J. Sorley, A. F. Wyatt. In the branch of Physical Chemistry: Arthur Bramley, B.Sc., A.R.C.S.; in the branch of Organic Chemistry: E. Anderson, O. L. Brady, A. D. S. Dawson, B.Sc., W. Jewell, J. A. McRae, M.A., W. G. Prescott, P. Schatz, D. B. Steinberg, B.Sc., J. C. White, L. Wilson, B.Sc.; and in the branch of the Chemistry of Food and Drugs, Fertilisers and Feeding stuffs, Soils and Water: H. J. Evans, Miss M. Gazdar, B.Sc., H. Lowe, B.Sc., W. R. Pratt, H. B. Stevens, J. A. L. Sutcliffe.

Of four candidates examined for the Fellowship, two passed in the chemistry of food and drugs, &c.: J. Hawthorne, B.A., Ph.D., and A. Miller, M.B., M.R.C.S., Major I.M.S.; and one in a special examination in metal chemistry: G. H. Stanley, A.R.S.M. One candidate for the intermediate examination presented himself at Singapore in June, and passed: A. M. Bailey. The board of examiners reported on 70 candidates altogether of these 44 passed.

Itchen (Hants.).—The Council have adopted a motion to apply for a provisional electric lighting order and to make inquiries of other authorities as to the cost of installing and running electric generating gear, &c.

King's Norton.—The Council have decided to commence at once the work of laying electric supply mains in certain streets which will be transferred to Birmingham Corporation on Nov. 9, but payment for laying the cables will not be made until after the date mentioned by Birmingham Corporation.

Lanarkshire Tramways.—On Tuesday the Board of Trade inspection of the extension of the Lanarkshire tramways from Motherwell to New Stevenston took place, and afterwards the new route was opened for traffic.

Leeds.—In moving the adoption of the minutes of the Tramways Committee at the Corporation meeting on Wednesday the chairman, Ald. C. F. Tetley, referred at length to the dispute with the tramway employés as to wages and hours.

In the course of the discussion the Lord Mayor announced that Mr. Askwith of the Board of Trade had offered his services in the dispute, and therefore the appointment of a special committee to deal with the matter was deferred until Mr. Askwith, K.C., had conferred with the men.

Llanelly.—On July 19 Llanelly & District Electric Lighting & Traction Co.'s tramways were formally opened. Messrs. Balfour, Beatty & Co., who constructed and equipped the line, were complimented by the local authority's representatives on the satisfactory work done and the straightforwardness of the whole of the negotiations.

London County Council.—On Tuesday sanction was given to the following loans for electricity supply:—St. Marylebone, £4,331, Woolwich £4,841, Hackney £4,364, Islington £5,500, and Poplar £34,995.

New Tramway Proposals.—The recommendations of the Highways Committee, authorising the Council to promote legislation in the next session of Parliament for the construction of seven new tramway lines (particulars of which were given in the last issue of THE ELECTRICIAN) was agreed to.

Loughborough.—The Council have received sanction to a loan of £2,200 for the electricity department.

Of this amount £1,930 is for turbines, &c., and is repayable in 19 years, and £270 for instruments and apparatus, in 15 years.

Luton.—The salary of the electrical engineer (Mr. W. H. Cooke) has been increased from £400 to £450, and that of the chief assistant (Mr. H. A. Kell) from £140 to £165 per annum.

Melrose (Scotland.).—The Town Council has granted the application of the Electric Supply Corpn. for consent to the erection of overhead wires from Melrose to Gattonside and Darnick. It has been practically decided to erect a power station to supply electricity to St. Boswells, Newtown, and Bowden.

Newcastle-Emlyn.—The Council last week accepted the offer of the local electric light company to light the whole of the urban area, including Aberarad, for one year from July 25.

Railway Electrification.—Mr. H. Cosmo O. Bonsor stated at the meeting of the S.E. & Chatham Railway Cos. on Friday that their auditor considered that the electrification of the Brighton Company's lines had had only a small effect as regarded competition with the South-Eastern Co.'s lines. The question of electrifying the North Kent lines had been before the board, but he did not think that, in itself, the electrification of the lines from Dartford to Charing Cross or Cannon-street would pay.

Reigate.—An unopposed inquiry was held last week into the Council's application for sanction to a loan of £8,400 for additional generating plant, &c.

Rosyth.—It is stated that schedules were issued on Saturday for the contracts for the erection of a power station in connection with the naval base at Rosyth. The cost of the power station is estimated at about £250,000 out of the total of £3,500,000 expected to be the total capital expenditure on the Rosyth naval base. The contractors for the work are Easton, Gibb & Co., who are sub-letting the contract for the power station.

Southampton.—The Northam main is to be doubled at a cost of £1,156, and mains are to be extended in the Bassett district at a cost of £155.

Sanction has been received to a loan of £5,700 for enlarging the trunk mains to Portswood and Shirley.

The borough electrical engineer (Mr. H. F. Street) has been instructed to obtain prices for a condenser and an air pump.

The Tramways Committee will put in hand the work of extending the loop at Highfield-road.

Southwark (London).—The Council last week adopted an estimate of £4,456 required for the electricity undertaking and decided to apply to L.C.C. for a loan.

Stoke-on-Trent.—The Federated Council have been notified by the L.G. Board, in reference to the Council's application to borrow £60,000 for electricity supply, that formal sanction has been given for £13,094 for laying cables, but deferring sanction for those portions of the loan required for buildings and plant.

Sunderland.—The Electricity and Lighting Committee have entered into a 10 years' contract for supply of electrical energy to the Sunderland Shipbuilding Co.

Swansea.—The Rural District Council is recommended to adopt electric lighting for Birchgrove on the terms arranged last year with Mr. Evan Lewis.

Digitized by Google

Trackless Trolley Traction.—A deputation from Edinburgh Council is to go to Leeds and Bradford in inspect the rail-less trolley system of traction, with a view to considering its suitability for Edinburgh.

Keighley Corporation have asked Bingley Council's consent to the running of rail-less trolley cars through Bingley to Nab Wood, and Bingley Council have decided to ask Bradford Corporation if they are disposed to run tramways or rail-less trolley cars to Bingley.

Walthamstow.—On Thursday last Mr. T. C. Ekin held a L.G. Board inquiry into the application of the Council for permission to borrow, amongst other sums, £5,149 for an additional feeder cable, and £1,485 for a branch feeder and stoneware conduits.

Mr. Spurr, the Council's electrical engineer, said the demand in one area up to June last was 117 per cent. in excess of the demand last year.

Coun. Pollard said that the electrical undertaking had been the making of the town from the industrial point of view.

Mr. English supported both applications on behalf of the Property Owners' Association.

Wimbledon.—On Tuesday an inquiry was held into the Council's application for sanction to borrow £7,459 for giving a supply of electricity to Maldens and Coombe.

Wireless Telegraph Notes.—It was announced last week that a captain and lieutenant (Messrs. Brenot and Menard) of the French Army had ascended from the military school at St. Cyr on a Farman biplane fitted with a new type of apparatus for wireless telegraphy, 500 metres over Rambouillet (which is about 35 miles from the Eiffel Tower). Evolutions were carried out, and a message of 22 words sent to the Tower, whence it was retransmitted to the War Ministry. An interesting feature of this transmission was that the message was also transmitted to Fez and to Metsinez (Morocco). The apparatus employed is said to weigh only 21 kilogrammes.

The French military authorities announced last week that regular wireless connection had been established between Paris and Fez (Morocco.)

It is announced that the Australasian Wireless Co., Ltd., has been formed at Sydney to take over the undertaking of Australasian Wireless (1909), Ltd., including patent rights for Australasia and British possessions in the South Seas, factory, plant, stock and installations, for £15,000 in 6 per cent. preference shares, £20,000 in ordinary shares, and £10,000 cash. 30,000 shares of £1 have been publicly subscribed, making the issued capital £65,000. The company has contracted to supply 2 high-power stations in the Commonwealth, 2 high-power stations in New Zealand, and 5 low-power stations to the steamers of the Union s.s. of N.Z., A.U.S.N. Co., Huddart, Parker & Co., and Howard Smith. The company operates the Telefunken system.

Workhouse Lighting.—At a meeting of York Guardians last week it was reported that a communication from the York city electrical engineer had been received stating that an extension of the electric supply mains was proposed, and asking guardians to adopt electric power and lighting at the workhouse. Estimates are to be prepared.

Worthing.—A L.G. Board inquiry was held by Mr. H. R. Hooper on Friday into the application of the Council for permission to borrow £4,950 for extensions of buildings and plant at the electricity works. It is proposed to put down two new 125 kw. generators driven by Diesel oil engines.

Sports.—The annual sports of the Croydon municipal tramway employés took place last week, when some good sport was witnessed.

Mr. J. Hammond won the Club Mile Cycle Handicap and the Tantalum Cup presented by Siemens Bros. Dynamo Works; L.C.C. Tramways (Belvedere) beat the P. Division of Police in the final of the Bovril Challenge Shield tug of war and "walked over" for the Tramways Cup tug of war. The tramways military band was one of the attractions, and the Mayoress distributed the prizes.

COLONIAL AND FOREIGN NOTES.

American Telegraphic Matters.—We are informed that the Postal Telegraph Co., which is the American Landline System of the Commercial Cable Co., has written an open letter to the Attorney-General of Texas setting forth :—

That a monopoly and combination in violation of the Anti-Trust Acts of that State has been brought about by the Western Union Telegraph Co. and the American Telephone and Telegraph Co. and their subsidiary companies, with the effect that 83 cities and towns in Texas and surrounding States, each having more than 1,000 population, have been cut off from telegraph competition, besides a much larger number of smaller towns, that competitive telegraph offices have been closed in 23 cities and towns in those States, and that the Postal Company is building into that territory as fast as the lines can be constructed. The Postal Company have already reached Dallas and Fort Worth and is far on the way towards Galveston and Houston, but in the meantime Texas, Oklahoma, Arkansas and parts of three other States are practically without competition in telegraphy on account of this combine.

This open letter, we learn, is in response to an inquiry by the Attorney-General, who is investigating the subject in accordance with a resolution of the legislature of Texas. The open letter ends as follows: "We can maintain offices in all of your chief cities and towns, and intend to do so, and you may rely upon it that when we open offices in those cities and towns they will stay open and will not pass under the control of the Bell Company or the Western Union. We shall not enter into any combination, neither shall we sell out. The Mackay interests are entirely able to take care of themselves and are strongly intrenched in finances, organisation and fast service, and are not afraid of what seems to be the crushing out campaign of the combine."

Australasia.—Mr. G. T. Elder has entered into a contract to supply electrical energy for lighting Mudgee (N.S.W.).

Perth City Council have had a report prepared by Mr. H. Edmiston on routes which could be followed in providing an electric tramway service to supplement that owned by the Perth Electric Tramways (Ltd.). The report deals with 13¼ street miles (= 18 miles single track), and the estimate includes £40,000 for rolling stock and various sums for car-shed, workshops, feeders, overhead equipment, &c., the total expenditure being £179,394, exclusive of cost of land (if any) and preliminary and legal expenses and street widenings (if necessary).

The Courts have sanctioned the proposal of the Morthake (Victoria) Butter & Cheese Factory to instal electricity generating plant to supply current for their own use and also for public lighting. An Order in Council has been applied for.

The action brought by the Ore Concentration Co. (1905) and the Australasian Ore Concentration Synd. against the Sulphide Corpn. for alleged infringement of the Elmore process, has been dismissed with costs.

Messrs. Lincolne and McDougall are preparing plans, &c., for the electric lighting of Rutherglen (Victoria).

The Minister of Public Works has authorised the erection of electric cranes at Carrington Wharf, Newcastle (N.S.W.)

The Electrical Employés Union (N.S.W.) are applying to the Wages Board for the following amendments of the Boards' award of June, 1910: Men on shift work on private installations, if required to work on public holidays, to have two week's leave annually on full pay, and if they work on holidays in addition to ordinary working days that they shall be paid at time-and-a-half rates, and that men who attend to steam and electric plants combined shall be paid 11s. a day.

Conditions are being arranged for supply of electricity by the Tallangatta Butter Factory to Towang Shire Council for lighting Tallangatta.

Mr. W. G. T. Goodman, chief engineer and manager of the Municipal Tramways Trust of South Australia, has been appointed to report on the proposal to construct an electric railway from Hobart to Huon (Tasmania).

The acting Premier of Victoria, the Hon. W. A. Watt, has promised to submit to Parliament a scheme for the electrification of the Melbourne suburban railways.

Bolivia.—A hydro-electric plant is being equipped to supply the town of Oruro with light and to work the new electric tramways to the villages on the outskirts.

The first Diesel engine in this district was ordered by Mr. T. J. Hoope M.E., for the Berenguela mines; a second of 350 H.P. is being erected for Mr. S. Patiño's Uncia mines, and a third (150 H.P.) has been ordered by the Electric Light Co. of Cochabamba.

The question of obtaining water-power from the rivers beyond Uncia to supply electric power to all the mines in the district has been considered but was found to be too costly.

A French firm of contractors has asked the Bolivian Government to contribute £150,000 towards the cost of construction of a metre-gauge railway to connect Sucre with Potosi, a distance of about 136 miles. It is proposed to use electric or petrol driven cars both for passengers and goods.

Brazil.—The Sao Paulo Tramway, Light & Power Co. (a company incorporated in April, 1899, under the laws of the State of Maine U.S.A.) exploits certain concessions for running street railways and for supplying electricity for light and power in the city of Sao Paulo. A considerable proportion of the capital was subscribed in the United Kingdom.

The company utilises a waterfall of the Rio Tiété (23 miles from the city), which is capable of developing up to 60,000 H.P., and electric energy is transmitted to the city by overhead cables. The company owns 105 miles of tramway, and supplies current for lighting to over 5,000 customers, using some 72,000 8 c.p. lamps, and power to over 500 customers using nearly 15,000 H.P. The working of the company has been successful from its inception, and good dividends have been paid. For 1910 after having paid a dividend of 13 per cent., £200,000 was placed to reserve and £273,000 carried forward.

Abundance of hydraulic power is one of the most valuable natural assets of the state. The principal falls are the Rio Grande (600,000 H.P.), Rio Parana (447,000 H.P.), Rio Tiété (159,300 H.P.), Rio Jaguer (50,000 H.P.) and Rio Branco (15,000 H.P.); total 1,271,300 H.P. There are also a large number of lesser falls, giving a further aggregate of 1,000,000 H.P. The water power already utilised is about 80,000 H.P.

Canada.—A "Standard" correspondent states that supply from the Winnipeg municipal power plant will be available this month

Digitized by Google

Negotiations are proceeding for the purchase by the Municipality of all the company's franchises—street railway, electricity, gas, &c.

It is expected that the Winnipeg hydro-electric generating station at Point du Bois will be working by Aug. 15, and that electrical energy will be transmitted to the receiving station in the city on that day. Mr. Chace, the engineer superintending the construction work, thinks the regular supply to customers will commence from two units of the power plant on Sept. 15. These first two units will generate about 4,000 H.P. each. According to present estimates three further units, making a total of about 20,000 H.P., will be ready and in commission by Dec. 1.

Copenhagen.—The Municipal Council took over the working of the town electric tramways on Tuesday.

Cuba.—According to the "Engineering News" a concession has been granted by the Cuban Government to the Cienfuegos, Palmera & Cruces Electric Power & Rly. Co., to construct approximately 450 km. (280 miles) of railway, to build dams, impound water and generate electricity.

The railway will have numerous branches to various sugar plantations on the south side of the island and will touch Rodas, La Isabella, Santa Clara, Caribarien, Salamanca, Placetas, Nazarene, Fomento and Zaza. Included in the concession is the right to use the public highways and to acquire private property where necessary. The concession further grants the use of all public waters on the Hanabanilla and Negros Rivers, where a hydro-electric plant will be erected to furnish motive power for the railway. No duties are to be levied on machinery or supplies imported in the operation or construction of the line.

France.—Frequent electric trains running in a tunnel 12 miles long, called the Galerie de la Mer, bring coal down from the mines of the Charbonnages des Bouches-du-Rhone at Gardanne to Cape Pinède into the port of Marseilles, and immediately over this tunnel at Les Aygalades a German firm (of Neuhausen) have established a factory for the extraction of alumine (carbonate of aluminium) from bauxite. The work can be carried on under best conditions, as coal is raised through a well from the tunnel, and water, electrical energy (from the power station at Janet) and caustic soda (from the Solvay works at Les Salins de Geràud) are all within easy reach.

The Provence shipyards established 11 years ago are thoroughly equipped with electric power. 34 ships were launched during 1910, one vessel being of 11,829 tons displacement and 538 ft. in length.

On July 21 a new law was published authorising Paris city authorities to borrow £9,600,000 for the completion of the Paris Metropolitan Railway.

Germany.—British Consul R. Bernal, at Stettin (Pomerania), reports as follows:—

Electric power stations are being erected in various parts of this province to supply towns, villages, estates and farms with electric light and power. Several of these stations are already working. They will be of great assistance to small farmers and artisans requiring power at a cheap rate, but there appears to be some doubt whether large landed proprietors will benefit to a similar extent. Up to the present steam engines have been used for agricultural purposes; it has, however, latterly been found that the cost of electric power is considerably higher. Current required for a threshing machine of average size is said to cost 2s. 1d. per hour; larger machines as now used would cost about £1. 5s. to £1. 10s. per 10 hours. Steam engines on the other hand consume about 7 cwt. of coal during 10 hours and 1 cwt. to 2 cwt. more when driving the larger threshing machines. For heavy agricultural machinery the steam engine would therefore be the more economical.

Mr. Bernal does not give his authority for these figures, nor other essential details.

Italy.—A new law was recently published allocating 3,210,000 lire (£128,400) for extensions to the State telephone system. Provision is included for the establishment of international lines as follow: Rome-Milan-Simplon, Turin-Milan, and Genoa-Milan, for communication with Germany; Milan-Swiss Frontier (Chiasso) and Milan-Swiss Frontier (Simplon), for direct communication with Bâle and Zurich.

The concession for the construction and working of an electric railway between Domodossola and the Swiss frontier has been formally awarded to Sig. J. Sutter.

The Societa anonima Elettrica della Sicilia Orientale has practically completed its plant for the supply of electric power in the Catania district of Sicily, and the Société Anon. Tramways et Eclairage Electriques à Catane is about to construct an electric tramway (in which the first-mentioned company is also interested) between Catania and Acireale.

South Africa.—The Postmaster-General of Southern Rhodesia recommends the erection of two additional copper telegraph wires along the railway from Salisbury to Bulawayo and Ramathlabama, at a cost of £20,000. He also proposes to introduce the double wire system in lieu of the existing single lines in the Bulawayo telephone system.

Spain.—Don Isidro G. Lastra has applied to the Public Works Department, Madrid, for a concession for the construction and working of an electric tramway from RENTERIA to the French frontier (province of Guipúzcoa).

Switzerland.—A consular report from Davos says that for some years activity has been shown in utilising the water power of mountain streams. About 17 years ago this source of power was used to supply the whole of Davos with electric light, small local installations having been at work for some years previously. The last few years have been marked by extraordinary development in this direction. In 1909 two mountain streams in the canton were employed to furnish electricity to Zürich—a distance of about 120 miles, at a cost of over £600,000, and during 1910 several new electricity works have been projected—two in the Engadine Valley, one at Sils, one at Bernina, and one in the Albula Valley. The Bernina scheme has been actually begun.

It is intended to run a branch line of the Rhaetian Railway, operated by electric traction, from Bevers to Schuls—the first step in the conversion of the cantonal railway network.

The "Berliner Tageblatt," says the work of the Swiss Commission for studying the electrification of the Swiss railways is progressing rapidly, and that a report will be published shortly dealing chiefly with the electrification of the St. Gothard Railway. The first route on which the electric service will be established is the Erstfeld-Biasca line. Capital expenditure is estimated at £800,000.

Trade with Brazil.—The Brazilian sub-section of the London Chamber of Commerce has presented to the Brazilian Minister in Great Britain a petition stating—

That at a meeting of Brazilian merchants held on Feb. 3, 1911, a resolution was unanimously passed expressing strong disapproval of the growing practice in connection with Brazilian trade of systematically undervaluing and misdescribing by means of fictitious invoices merchandise and machinery shipped to Brazilian ports; that this practice involves a considerable loss of revenue to the Brazilian Government, and is detrimental to the legitimate interests of those merchants who refuse to undervalue or misdescribe goods exported from the United Kingdom to Brazil; and that many of the other leading Chambers of Commerce in the United Kingdom, France and Germany, have confirmed the existence of the practice complained of, and have expressed in communications to the London Chamber of Commerce their strong condemnation thereof. The petition concludes by asking His Excellency to represent to the Brazilian Government the desirability of taking such steps as may be found possible to repress the practice complained of.

His Excellency has replied that a communication has been made to the proper department of the Federal Government.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Barnstaple.—The accounts of the electricity supply department for the year ended March last show capital expenditure £32,581 (increase £396), of which £6,536 has been repaid.

Revenue was £4,700, working and general expenses were £3,259, gross profit was £1,441, interest on debt required £857 and on overdraft £121, and instalment of principal repaid was £1,010, total £1,988, so that there was a deficiency for the year of £547, of which £209 has been transferred from general rate and the debit balance of £347 carried forward. Units generated were 347,581 (compared with 308,644 in previous year), 83,161 (79,240) were supplied to public lamps and 193,725 (157,142). There are 30 arcs and 183 osrams for public lighting. The total maximum demand was 255 kw. (248 kw.).

Barrow-in-Furness.—The accounts of the electricity department for the year to March last show capital expenditure £115,478 (increase £908), of which £30,167 has been repaid.

Income was £14,435 (against £13,266 in previous year) and gross profit £8,028 (against £7,384). After providing for interest and sinking fund there remained £706 (against £229), which has been placed to renewals fund. The combined maximum load was 951 kw. (925 kw.), and the combined load factor 14·99 (13·95) per cent., the traction load factor being 23·26 (22·08) on the 150 kw. generator employed. The units sold were 1,249,163 (1,130,092). There are 88,979 (83,419) equivalent 30 watt lamps connected, and the units sold per lamp (exclusive of traction) were 10·9 (10·4). The average price obtained for the total supply was 2·717d. (2·759d.) per unit. Fuel cost 0·404d. (0·420d.) per unit sold, works costs were 0·909d. (0·912d.) and total cost (exclusive of capital charges) was 1·231d. (1·249d.).

Birkenhead.—The income of the electricity department for the year ended March 31 was £25,826, including £20,542 from the sale of current by meter, and £40,26 from the tramways department, the balance being made up of motor and meter rental, &c.

The working expenses were £15,281, leaving a gross profit of £10,545. Interest and dividends on stock, &c., absorbed £5,082 and sinking fund £4,171 and after paying bank interest, income tax, &c., the balance (£952) was transferred to the district fund. The capital expenditure is £160,368, an increase of £2,889.

Bootle.—The accounts of the electricity supply department for the year to March last show capital expenditure £115,393 (increase £765), of which £38,380 has been repaid.

Revenue was £20,413, working and general expenses were £10,256, gross profit was £10,157, to which is added £394 income tax. £54 in-

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

terest on money at deposit and 17s. 9d. interest on free wiring accounts. Interest required £2,507, repayment of principal £2,044 and sinking fund £2,255, reserve fund was increased by £2,300, to £11,078, and £1,500 has been applied to reduction of local rate. Units generated were 3,341,081, sold to public lamps 291,229, by contract 1,250,534, by meter to private consumers 1,498,950. There are 493 public lamps, including 174 arcs. The total maximum demand was 1,461 kw.

Carlisle.—The accounts of the electricity department for the year ended March last show capital expenditure £87,933 (increase £17,573), of which £25,746 has been redeemed.

Revenue was £14,833, and gross profit was £8,768 (increase £849) and net profit £3,346 (increase £296). The report of the city electrical engineer (Mr. S. T. Allen) says production costs, including management, rates and taxes, &c., but not capital charges, were £1,136 higher than those of the previous year (increase 24 per cent.), but the units sold increased 27 per cent., and the coal cost 10 per cent. more per ton. Interest and instalment of debt increased £486. Power units sold increased by 372,875, public lighting by 611 and miscellaneous 3,115, while private lighting decreased by 22,125 and tramway supply by 4,262, the total sold being 1,649,211 out of 2,076,793 generated. The decrease in lighting units is due to the use of metal filament lamps, although there is a steady increase in the number of lamps connected, and over 2,500 were connected during the year. Motors of 768 H.P. were connected during the year. Fuel per unit sold cost 0·26d. (against 0·24d.), and total works costs were 0·85d. (0·87d.).

Eccles.—The accounts of the electricity department for the year ended March show capital expenditure £55,508 (increase £4,266), of which £6,704 has been redeemed.

Revenue was £10,107 and gross profit £4,536, and after providing for capital charges, income tax, &c., and transferring £90 to capital account for excess expenditure, there was a surplus of £965, which has been placed to reserve. Units sold were 425,878 to private consumers, 764,285 for tramways and 97,225 for public lighting.

Heywood.—The accounts of the electricity department for the year ended March show capital expenditure £32,070 (increase £3,684), of which £14,945 has been repaid.

Revenue was £4,962 (against £5,037 in previous year), working expenses were £3,713 (£3,480), gross profit was £1,249 (£1,557). But interest and sinking fund contributions required £1,901 (against £1,433), so that the deficiency for the year was £652. In the report of the electrical engineer (Mr. Jas. Stott) it is stated that the interest and sinking fund on the last extension are included for the first time in the accounts. The units generated were 686,036 (against 674,228 in previous year), and 91,794 (95,705) were supplied for public lighting, 170,853 (69,766) to motors, and 418,889 (504,757) for traction. The decrease in consumption for private lighting is caused by the installation of metal filament lamps and the traction demand by reduced service and careful driving. Coal cost 0·53d. (against 0·57d.), and total working expenses were 1·22d. (1·23d.). The average price received was 1·71d. (1·78d.) per unit. The financial result of the year's working was due to the amount of capital the department has to repay in three years, and Mr. Stott considers it is scarcely equitable treatment for the L. G. Board to say that such a sum must be provided in so short a time, as the plant which has been cast out was not unworkable, but small and uneconomical.

The capital expenditure on the tramways is £66,624 (including £22,947, the amount of award to the Bury, Rochdale & Oldham Tramways Co.), and the loans extinguished and the mortgage sinking fund amount to £7,409. Revenue was £10,964 (£11,207), working expenses were £7,515 (£8,339), gross profit was £3,449 (£2,868), interest and sinking funds required £4,853, showing a deficiency of £1,404. Passengers were 2,084,396 (against 2,181,751), car-miles 275,064 (288,087), and units used 418,889 (504,757), or 1·52 (1·75) per car-mile.

Ilford.—In presenting the annual report of the electricity undertaking for the year ended March 31 Mr. Philpot stated last week that the mechanical stokers had acted so efficiently that while 147,000 more units had been generated the cost of coal had only increased by £5. £2,000 more had been received from their consumers than in previous years. The undertaking had been in existence just 10 years. Up to date they had borrowed £181,000, and had repaid £37,000 of capital.

King's Lynn.—The capital expended on the electricity undertaking at March 31 last was £50,766, an increase of £280.

Revenue was £6,983 (against £6,856) and working expenditure £2,569 (£2,508). Total expenses were £5,949 (£6,018) and the net profit was £1,034 (£838), of which £280 has been transferred towards expenditure on meters and £300 to district fund in relief of rates. Units generated were 525,520 (against 502,321), supplied to public lamps 129,311 (132,103), supplied for private lighting by meter 211,412 (191,669) and by contract 5,871 (5,670) and to motors and heating 132,163 (128,219). The total number of (equivalent) 8 c.p. lamps connected is 36,816 (increase 2,000). The maximum supply demanded was 345 kw. (330 kw.), and the combined load factor 15·84 (17·41). The total horse-power of motors connected is 411 (355). Fuel cost 0·44d. (0·45d.) per unit, works costs were 0·90d. (0·92d.), total costs were 1·29d. (1·31d.), or 2·99d. (3·15d.) including capital charges. Total average price obtained was 3d. (3·04d.) per unit.

Marylebone (London).—The accounts of the electricity department for the year ended March last show capital expenditure £2,051,160 (increase £23,884), of which £153,359 has been repaid or provided for repayment.

Revenue was £176,318 (against £166,572 in previous year) and gross profit was £125,878 (£121,669). Interest and special charges absorbed £75,052 (against £76,514), provision for repayment of loans £38,738 (£36,673) and the net profit was £12,089 (£8,482). Coal cost 0·268d. (0·288d.) per unit sold; generation costs were 0·432d. (0·498d.) and distribution 0·150d. (0·139d.), total working costs 0·901d. (0·961d.). Capital and special charges were 2·226d. (2·52d.) Total connections, in kilowatts, at March last were 20,643 (against 19,084 at March, 1910), including private lighting 14,992 (14,737), motors 2,486 (2,117), heating and other uses 2,771 (1,972), public lamps 393 (258) and street lighting by private lamps 1 (nil). Units generated were 15,881,452, supplied to public lamps 1,397,585 and to private consumers by meter 10,939,371, total sales being 12,336,956 (against 10,776,459). There are 87 arc and 3,516 incandescent lamps for public lighting. Maximum load was 8,333 kw. Expenditure on sales and publicity department for the year was £19,171 and the amount received for sale of apparatus, hire purchase, hire and maintenance, £16,959.

The report of the Electric Supply Committee is that electric cooking ranges can now be offered which are reliable and strongly competitive in running cost with other forms of cooking apparatus. The department bears the cost of negotiating agreements and contracts with consumers for all purposes, and there is frequently no income to set against the cost, when, as is often the case, the actual work goes to wiring contractors, but the main object is achieved, which is increased income from sale of current. Several agreements have been concluded which overcome the practice of farming out the supply of electricity by landlords of flats, which confined the tenants to the use of electricity for lighting only. This has thrown open a wide and lucrative field for the introduction of "other uses" of electricity. Consumers who have accepted the "telephone" system of charging are consuming electricity for heating and cooking in ever-increasing quantities. The figures relating to the sale of apparatus and work done for consumers show a substantial margin over prime cost, although they include apparatus sold and work done for contractors, builders and the Council, on which the margin is small. The results show that the statement that the department cuts prices and competes unfairly with contractors is, it is understood, without foundation in fact.

Stoke Newington (London).—Last week the Electric Lighting Committee reported that the accounts of the electricity undertaking showed that had Schedule II. of the agreement with the North Metropolitan Electric Power Supply Co. been in operation during the year ended March 31 last, a profit would have been secured to the Council of £223. 8s. 3d., after payment of all working and management expenses and loan charges; and that the total repayments of loans at March 31 were £3,610. 13s. 1d., and the Committee recommended that notice to terminate Schedule I. of the agreement at March 31, 1912, be given to the company. Consideration of this proposal, which, if acted upon, will place the entire management and control of the undertaking in the hands of the Borough Council, was deferred until the September meeting.

Wolverhampton.—The accounts of the electricity supply and tramway undertakings for the year ended March 31 were recently approved by the Council.

The total revenue of the electricity department was £49,935 (against £40,791 in 1910) and included £45,047 from the sale of current for private and public lighting and power. The expenses were £26,460, against £20,429, and after allowing £250 for bad debts, the gross profit was £20,225. Interest and sinking fund required £15,222 (£14,762) and after paying income tax (£140), &c., the net balance was £5,231 (£5,297). 12,981,989 units were generated and 10,818,089 units were sold: 196,918 units supplied to the public lamps, 8,165,344 to private consumers for power and light and 925,192 by contract and 1,530,635 to the tramways department. There are 62 arc and 231 incandescent lamps (against 62 and 207 respectively) for street lighting. The maximum load was 4912kw. (4,180 kw.) and the equivalent of 249,620 30-watt lamps (224,071) is connected. The decrease in the net profit is attributed to abnormal expenditure on repairs and maintenance, wages and material on capital account charged to revenue, renewals of plant and reduction in price of current for traction, and under the circumstances the result of the year's trading is considered very satisfactory, as the works costs were 0·557d. against 0·562d. There was an increase of 40 per cent. in the units sold for power, 17·6 per cent. for private lighting, 5 per cent. for traction, and 2·6 per cent. for public lighting. The increase in revenue from private

Digitized by Google

lighting is extremely good and was the largest since 1903. The number of new consumers connected was the largest in the history of the undertaking. During the year £807 excess expenditure on capital account was charged to revenue, as were £687 for house services and £210 for "free" wiring. In future the Committee will allocate all future expenditure on "free" wiring to revenue or reserve fund. Motors of 769 H.P. were added during the year, and, apart from the important contract with Messrs. Bayliss, Jones & Bayliss, the demand for power is advancing very satisfactorily.

The receipts of the tramways undertaking were £49,710 (against £45,500), including £48,611 passenger receipts and £298 from parcels. The expenses were £28,892 (£27,585) and the gross profit was £20,818 (£17,915). Interest was £7,714, and after paying income tax and other items and crediting interest on investments, the balance was £13,113. The repayment of loans and sinking fund required £4,847, and £4,118 was placed to renewals and £2,023 to reserve fund, and the balance (£2,125) was devoted to relief of rates. 10,646,802 passengers were carried (against 9,670,657) and 1,126,607 (1,030,720) car-miles run. The gross capital expended is £277,410. The Committee are pleased with the reduction of 0·268d. per car-mile in the total working costs (6·155d. against 6·423d.) for the year.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1911 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 24th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1911 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

The COMMISSIONERS OF H.M. WORKS AND PUBLIC BUILDINGS are required to receive tenders for the supply of electrical accessories for three years from Sept. 1 next. Forms of tender and particulars from the Storekeeper, H.M. Office of Works, 12, Lambeth Palace-road, S.E. Tenders by Friday Aug. 18 to the Secretary, H.M. Office of Works, Storey's Gate, London, S.W. See also an advertisement.

The Council of the County Borough of WEST HAM invite tenders for (a) water tube boilers, (b) coal handling and discharging plant, (c) 1,000 kw. turbo-alternator, with condensing plant, (d) river service pipework, (e) centrifugal pumps, (f) 750 kw. converter (two-phase to d.c.). Specification, form of tender, &c., from Mr. H. H. Couzens, engineer and manager, 84, Romford-road, Stratford. Tenders to the borough clerk, Mr. Fred E. Hilleary, Town Hall, Stratford, E., by 10 a.m. on Thursday, Aug. 31. See also an advertisement.

The asylum of the Lancashire Asylums Board, WHALLEY, near Clitheroe, is in course of erection, and the Committee of Visitors will shortly be prepared to let the contract for the electrical plant. Contractors must send names and addresses by Aug. 7 to Mr. Viscount E. Clere, clerk to the Committee of Visitors, County Offices, Preston. See also an advertisement.

Tenders are invited up to Sept. 26 for the supply of telephone material and 30 miles of telephone cable to the Postmaster-General's Department in VICTORIA. Specifications, forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited for the supply of a desiccating plant, to the Postmaster-General's department in NEW SOUTH WALES. Forms of tender, specifications, &c., may be obtained from the Commonwealth Offices, 72, Victoria street, London, S.W. See an advertisement.

Tenders are invited up to Sept. 5 for the supply of (*a*) 10,000 protectors and (*b*) sundries to the Postmaster-General's Department in VICTORIA. Tender forms and specifications at the Commonwealth Office, 72, Victoria-street, London, S.W. See an advertisement.

BIRMINGHAM Corporation require tenders by noon Aug. 18 for erection of a tramway depot in Whitmore-street, Hockley, Birmingham. Particulars from Mr. A. Rowse, King's Court, Colmore-row, Birmingham.

ABERDEEN City District Lunacy Board want tenders by 5 p.m. Aug. 14 for electrical and other works in connection with the erection of a new steading on Nether Kingseat Farm, Newmachar. Plans, &c., with Messrs. D. & J. R. M'Millan, 105, Crown-street, Aberdeen.

Tenders are invited by the FARNHAM GAS & ELECTRICITY CO. for the supply and erection of two high-speed Diesel oil engines coupled to two 90 kw. alternators with direct-coupled exciters, piping, tanks, overhead traveller and accessories, and main high-tension switchboard. Specifications, &c., may be seen at, but not obtained from, the offices of the consulting engineers (Messrs. Handcock & Dykes), 11, Victoria-street, Westminster, S.W., and obtained from the Secretary, to whom tenders by noon Aug. 16.

BRUMBY and FRODINGHAM Council require tenders by Aug. 11 for supply and erection of poles, lamps, wires, &c., for lighting the streets electrically. Specifications, &c., from the Council Offices.

WARRINGTON Electricity and Tramways Committee require tenders by noon, Aug. 9 for a motor-driven induced draught fan. Specification, &c., from the Borough Electrical Engineer.

The Metropolitan Water and Sewerage Board, BRISBANE (Queensland) require tenders by noon Jan. 30, 1912, for supply and erection of (alternatively) two or three units of pumping plant (including power generating plant), to deliver 6,000,000 gallons of water at an elevation of 400 ft. per day. Forms from the Agent-General for Queensland.

Tenders are invited for the supply of 530 a.c. meters, 495 d.c. meters and 133 maximum demand indicators to the City of MELBOURNE, Australia. Copies of specification, conditions of contract and form of tender from the agents for the City Council (Messrs. McIlwraith, McEacharn & Co. Propy. Ltd.), Billiter-square Buildings, London, E.C., to whom tenders are to be sent by noon Wednesday, Aug. 9.

Tenders are invited (up to Aug. 15) for the supply of (*a*) 80,000 insulators and (*b*) indiarubber covered wire to the Postmaster-General's Department in VICTORIA; up to Aug. 16 for cable, conduits, c.i. pipes, iron poles, insulators, wires, &c.; up to Aug. 23 for the supply of letter box fronts to the Postmaster-General's Department in QUEENSLAND; up to Aug. 23 for telegraph, telephone and electric lighting material to the Deputy Postmaster-General in NEW SOUTH WALES; and up to Aug. 30 for supply of porcelain insulators, copper wire, sleeves, &c., to the Postmaster-General's department in SOUTH AUSTRALIA. Specifications, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders are invited up to Aug. 23 for the supply of telegraph and telephone material to the Postmaster-General's Department in SOUTH AUSTRALIA. Specifications, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W.

The Metropolitan Water and Sewerage Board, Albert-street, BRISBANE, Queensland, want tenders by noon Jan. 30 next for supply and erection, of one, two or three complete units, each consisting of power generating plant and pump or pumps to lift not less than 6,000,000 gallons per day. Particulars from the Secretary.

WELLINGTON (N.Z.) Corporation require tenders by 4 p.m. Aug. 24 for supply of a motor power waggon and accessories for the electric tramways department. Gonville and Castlecliff Tramway Board, Ridgway-street, WANGANUI (N.Z.) require tenders by 4 p.m. Aug. 14 for supply of overhead tramway material, feeders, &c. Conditions, &c., can be seen at 73, Basinghall-street, London, E.C. Representation in New Zealand is necessary.

The Municipal Council of BUDAPEST, Hungary, require tenders for the manufacture and supply of plant for a steam-driven electrical generating station, including two groups of three-phase turbo-generators (5,000 kw. each), 10,000 volts 50 cycles, boiler equipment for mechanical output of 5,000 kw. with reserve, pipeline, central switching and accessory equipments, travelling crane for engine room and coal-conveying plant. Specifications, &c., can be obtained at the Presidial Section of the Council, 9: IV., Városház-utca 16, II. 1, Budapest. Tenders by 11 a.m. Sept. 30.

Tenders are wanted by Aug. 15 for the equipment of electric power works, and the provision of a system of telephones and an electric lift, at the Danviks Hospital, STOCKHOLM. Specifications from the Elek-

Digitized by Google

triska Radfragningsbyran, Rosén och Waldenström, Regeringsgatan 20, Stockholm, on payment of deposit of 55/6.

Tenders will be received at the Town Hall, SYZRAN, Russia, on Oct. 14, for the construction of an electric tramway and the supply of electrical energy for lighting.

The time for the receipt of tenders by the Ministry of Public Works, Constantinople, for an electric power and tramway concession for JERUSALEM, is extended to Sept. 13. Specifications (in French) can be seen at 73, Basinghall-street, London, E.C.

The Public Works Department, Madrid, will receive tenders on Sept. 20 for the concession for the construction of the RENTERIA electric tramway.

Tenders will be received at the Electricity and Water Offices, BREMEN, on Aug. 14 for supply of transformers.

TENDERS RECEIVED AND ACCEPTED.

London County Council have received the following tenders for roadwork and platelaying, exclusive of supply of rails and special trackwork in connection with the construction, on the overhead trolley system, of tramways from Brixton-road to Herne-hill, via Effra-road and Dulwich-road. (The tenders also contain provision for certain paving works outside the tramway tracks in connection with street widenings along the route).

	Tramway works.	Paving works.
Kirk & Randall (*accepted*)	£18,104 9 0	£9,004 11 10
Dick, Kerr & Co.	18,950 4 6	8,653 16 2
Geo. Wimpey & Co.	18,407 6 10	9,250 2 2
A. N. Coles	19 010 7 10	9,681 0 3
John Mowlem & Co.	19,846 15 8	9,002 5 11
W. Underwood & Bro.	20,681 0 4	9,962 7 5
Chief engineer's estimate	19,616 0 0	9,500 7 1

London County Council have also received the following tenders for the execution of the roadwork and platelaying, exclusive of supply of rails and special trackwork, in connection with the adaptation and reconstruction, on the underground conduit system of electric traction, of the tramways in Seven Sisters-road, between Stroud Green-road and Green-lanes, in Green-lanes and Southgate-road, &c. (The tenders also contain provision for certain paving works outside the tramway tracks in connection with street widenings):—

	Tramway works.	Paving works.
John Mowlem & Co. (*accepted*)	£66,646 2 2	£5,347 0 8
Kirk & Randall	67,015 0 0	5,616 6 0
A. N. Coles, Plymouth	67,686 1 3	5,350 17 2
Dick, Kerr & Co.	67,750 15 0	5,788 10 6
William Underwood & Bro.	80,505 19 6	5,444 13 10
Chief engineer's estimate	68,727 9 5	5,418 5 7

London County Council have also authorised the expenditure of a sum not exceeding £400 for supply and laying of points, crossings, &c., for special trackwork in connection with the Hammersmith-Harlesden tramways, and the points, crossings, &c., are to be obtained from Hadfield's Steel Foundry Co. and laid by Geo. Wimpey & Co.

London County Council have sealed a contract with the British Westinghouse Electric & Mfg. Co. for supply of standard type controllers, electrical interlocking gear and additional cables for 100 double-deck electric cars at £6,390 (including an allowance to be made by the company of £195 in respect of 10) sets of existing controllers and switches).

London County Council have also accepted the tenders of Buck & Hickman (£1,565. 12s. 10d.) and Pollock & McNab, Ltd. (£524) for supply of plant and tools for the central car repair depot.

Southampton Council has received the following tenders:—

Surface condenser: Willans & Robinson (*accepted*) £730; Mirrlees Watson Co., £750; John Musgrave & Sons, £775; Cole, Marchent & Morley, £806; Richardsons, Westgarth & Co., £860. For a 200 kw. two-phase synchronous motor: Electric Construction Co. (*accepted*), £655; British Westinghouse Co., £670; British Thomson-Houston Co., £714; Maudsley's Ltd., £760; Lancashire Dynamo & Motor Co., £847; Dick, Kerr & Co., £988.

Swindon Council have accepted the following tenders:—

Tudor Accumulator Co., battery, £1,482 and £119 per annum for maintenance; Chloride Electrical Storage Co., automatic reversible traction booster and switchgear, £1,029; Electric Construction Co., three-wire hand-regulated booster, £275.

"Commercial Intelligence" announces that the following were the tenderers, through their local agents, for the supply of 21 miles of waterproof electric cable to Shanghai Municipal Council:—

Felten & Guilleaume Carlswerke (accepted); Arnhold, Karberg & Co.; General Electric Co.; United States Steel Products Co.; Bergmann Electrical Works; W. T. Henley's Telegraph Works Co.; Union Cable Co.; British Insulated & Helsby Cables; Callender's Cable & Construction Co.; Siemens Bros. & Co.; and Dr. Cassirer & Co.

At their last meeting, Holborn (London) Council formally accepted the joint tender of the Gas Light & Coke Co. and the Metropolitan Electric Supply Co. for street lighting at £7,654 per annum.

Luton Council have placed an order with the Hudson Economiser Co. for a cooling tower at £637. 10s., and that of Hayward, Tyler & Co. for a motor-driven feed pump at £120.

King's Norton Council have placed an order for the supply and laying of electric cables with Callender's Cable & Construction Co.

Eccles Council has accepted the tender of Korting Bros. for supply and delivery of a motor-driven centrifugal pump at £185.

The tender of Babcock & Wilcox has been accepted by Salford Council for the supply and erection of a water-tube boiler, superheater and mechanical stokers at £2,025.

Gloucester Electricity Committee have accepted the tender of Drysdale & Co. for a circulating pump at £135.

The tender of C. Suckling & Co. (at £65) has been accepted for wiring the Hendon hospital.

Peterborough Council have accepted the tender of G. Andrew & Co. for electric light fittings for Lincoln-road schools.

Bridlington Council have placed an order with A. C. Dickins for electrical fittings for the St. John-street schools.

York Council have accepted the tender of Callender's Co. for h.t. cables at £2,640.

The contract for the electric lighting at Victoria Hospital extension, Burnley, has been secured by Mr. R. B. Beattie.

Belfast Corporation have accepted the tender of the Ree Roturbo Mfg. Co. for a circulating pump, and that of the Worthington Pump Co. for a motor-driven air pump.

Wireless Telegraph Contract.—The "Marconigraph" states that a contract has been entered into by the Marconi Wireless Telegraph Co. and the Italian Government for the erection by the company of a 60 kw. station in the vicinity of Rome.

The building, masts and material are being supplied by Marconi's Wireless Telegraph Co., the erection of the masts being carried out through the intermediary of the Italian agency. Six towers in iron and wood of the Coltano type are being erected, two each being 75 metres high, and the remaining four each of 45 metres in height. These will support a multiple wire T aerial of a total length of 360 metres; the surface occupied by the aerial will be about 14,000 sq. metres. The Italian Government are erecting the building, which will contain engine power, battery and operating rooms, stores, waiting and staff rooms, and the necessary adjuncts. In the engine room, which will have a floor space of 32 ft. by 25 ft., there will be installed duplicate 50 B.H.P. Diesel oil engines, each driving, by means of a belt, a 30 kw. continuous current dynamo. Two 32 kw. low-frequency inductances will be provided for regulating the frequency of the discharge circuit to the value necessary for the number of sparks adopted, and, in addition two 32 kw. high tension transformers will be installed to transform the alternating current by the group of generators to the required voltage for the condensers. The receiving apparatus will consist of a valve receiver adapted to receive all words comprised between 2,650 and 6,500 metres. In addition to the valve receiver, a magnetic detector will also be furnished. The station is to test to Poldhu, and will have a normal power of 32 kw., and overload up to 100 kw. The exact arrangement of the plant for this overload has not yet been determined.

Commonwealth Contracts.—The Postmaster-General's Department in New South Wales have accepted the following tenders:—

Western Electric Co., telephone switchboard cable; Gibbs, Bright & Co., paper-insulated lead covered cable. The following are successful tenderers for the supply of telephone, telegraph and electric light material for 1911:—Western Electric Co., Jas. Paton & Co., British Insulated & Helsby Cables, General Electric Co., Noyes Bros., W. T. Henley Telegraph Works Co., R. J. Connolly, W. G. Watson & Co., Lawrence Hanson, British & Foreign Indent Co., Siemens Bros. Dynamo Works, India Rubber, Gutta Percha & Telegraph Works Co., Bullers (Ltd.), F. G. King, Haes & Eggers, Vacuum Oil Co., British Ever Ready Electric Co., Acme Bolt & Nut Co., Thornton & Watson, Williams & Co., Thesen Zwicker & Co., R. Johnson, Clapham & Morris, Geo. Cradock & Co., Brownlow, and H. A. Burnside.

The Victorian Railways Department have accepted the tender of Alfd. Adams & Co., for 50 electric bells, £179. 7s. 6d.

BUSINESS NOTICE.

Mr. Henning Proe, engineer and importer of electrical plant and other machinery, has opened offices and showrooms at 343, Re street, Sydney, N.S.W.

Summer Holidays.—The works and offices of the Electric Ordnance Accessories Co. (Ltd.), Aston, Birmingham, will be cl from the evening of Aug. 4 till Aug. 14.

The Dalston offices and stores of Siemens Brothers Dyna Works will be closed from Aug. 7 to 12.

The White Electrical Instrument Co. (formerly Electrical Dept Jas. Pitkin & Co.), Clerkenwell, London, give notice of closing fr Aug. 7 to 12.

The works and offices of the Crypto Electrical Co., Bermonds street, London, will be closed from noon Aug. 5 until Aug. 14.

In each case a small staff to deal with "urgent" matters will retained.

Sales by Tender.—Owing to their taking supply from the Dist Council, the directors of the Rugby School Electric Lighting

Digitized by Google

invite tenders for 100 B.H.P. and 75 B.H.P. Crossley gas engines, two Tulli's belts, 50 kw. Mordey and 35 kw. Brush alternators (with exciters), 2,000 volts, 100 periods, Dowson gas plant, five cooling tanks, boiler, switchboard, instruments, gas meter and sundry transformers and meters. Tenders to Mr. A. E. Donkin, Iverley House, Rugby, by Aug. 19. The plant can be seen by appointment. See advertisement.

Pursuant to an order of the High Court, tenders are invited for the purchase of the undertaking carried on by F. A. Glover & Co. (Ltd.) (in liq.) at Vine-street, E.C., and Maclise-road, Kensington, London, and at Windsor (as Windsor & District Electrical Co.), Slough (as Slough & District Electric Lighting Co.), and at Caversham, together with the stock-in-trade, works, plant, &c., at the London businesses and branches. Tenders by noon of Aug. 31 to the receiver (Mr. A. F. Whinney, C.A.), 4B, Frederick's-place, Old Jewry, London, E.C. Particulars and conditions, with forms of tender, from the Receiver, and of Messrs. Mills & Morley, solicitors, 38, Lincoln's Inn Fields, London, W.C. See also an advertisement.

Patents Development.—The proprietor of patent No. 29,363/1904, for "Improvements in and relating to electrical measuring instruments" desires to enter into arrangements by way of licence and otherwise for ensuring the development and practical working of same in this country. Apply to Messrs. Haseltine, Lake & Co., Chartered Patent Agents and Consulting Engineers, 7 and 8, Southampton-buildings, Chancery-lane, London, W.C.

The proprietor of patent No. 18,842/1907, relating to "Means for receiving intelligence communicated by electric waves," wishes to dispose of the patent or to grant licences. Applications to Messrs. Cruikshank & Fairweather (Ltd.), 65 & 66, Chancery-lane, London, W.C.

"The Journal."—Part 203 of the "Journal" of the Institution of Electrical Engineers is now ready, price 5s. Particulars of contents are given in an advertisement.

BANKRUPTCIES, LIQUIDATIONS, &c.

A dividend is to be paid to creditors of John D. Carlmark, electrical engineer, 402, High-street, West Bromwich. Claims to Mr. A. S. Cully, 191, Corporation-street, Birmingham, by Aug. 12.

Alfd. Sitch, electrical engineer, &c., 77, Brecknock-road, London, has been adjudicated bankrupt.

A meeting will be held on Aug. 14 at 2, Coleman-street, London, E.C., to receive an account of the winding up of the Buchholtz Reversible Turbine Synd.

On Tuesday meetings of creditors and contributories were held in the liquidation of J. G. Childs & Co. (Ltd.), Hawthorn-road, Willesden Green, N.W.

Mr. H. E. BURGESS, senior assistant official receiver, reported that the statement of affairs showed unsecured liabilities £20,640, assets valued at £3,410. The receiver appointed on behalf of a debenture holder for £5,000 estimated the assets at £2,000 or £2,500, and it did not appear likely, therefore, that the unsecured creditors would receive any dividend. The company was formed in Dec., 1901, to take over the business of electrical engineers previously carried on by J. G. Childs. The purchase consideration was about £7,300, of which £5,300 was payable in shares. The trading of the company had resulted in a loss throughout, the total during the company's existence being £15,000. Certain patents taken out by Mr. Childs relating to wind turbines were considered to be valuable, and he did not think those patents were included in the estimate of assets. The liquidation was left with the O.R.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*NOTE.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

May 29 1911.

12,792 BALL & LINGARD. Electric telegraph insulators and the like.
12,828 SMITH, MAJOR & STEVENS, MAJOR & KENNARD. Electrical reversing apparatus for remote control.
12,860 BARTON & SONS & HARPER. Fittings for electrical conduits.
12,896 DUNTON. Signalling devices for telephone systems.*
12,907 PETSCHAUER. Telephonic relays.
12,918 B.T.-H. Co. & F. WHITAKER. System of electric distribution.
12,919 B.T.-H. Co. & J. WALLACE. Electric switches.
12,920 B.T.-H. Co. (G.E. Co., U.S.) Casting copper articles.
12,921 ALLGEMEINE ELEKTRICITATS-GES. Systems of electric motor control. (Convention date, 27/5/10, Germany.)*

May 30. 1911.

12,993 PERRY. Electrical heating apparatus.
13,041 RUSSELL & SAUNDERS. Electric solenoid railway carriage and safe lock.
13,064 WILKINSON. Electric resistances for electric heating and cooking apparatus.
13,065 BRUSH ELECTRICAL ENGINEERING Co., SALISBURY & MILLS. Electric conductors for vacuum apparatus and method and means of sealing same into quartz and the like.
12,976 AKTIESELSKABET HOVLANDS RADIOTELEGRAF. Electric condensers. (Convention date, 1/6/10, Norway.)*
12,978 SCHIEFERSTEIN. Means for varying the inductance of electric circuits. (Convention date, 30/5/10, Germany.)*
12,984 MOORE & SHARDLOW & Co. Terminals for ignition plugs, magnetos and other electrical connections.*
13,014 BURGESS & SHAND. Discharging excess of electrical pressure.
13,020 MARCONI & MARCONI'S WIRELESS TELEGRAPH Co. Installations for wireless telegraphy.
13,021 B.T.-H. Co. (G.E. Co., U.S.) Electric conductors.*
13,026 FRIEDREICH. Supporting devices for electric illuminating bodies. (Convention date, 30/5/10, Austria.)*

May 31. 1911.

13,037 HARRIS & DEE. Non-corrosive terminal for accumulators.
13,099 ROSENBERG. Generation of alternating electric current.
13,100 SCHNEIDER. Recording and reproduction of telephone communications.
13,102 AKON. Systems for electrically controlling the operation of time indicating devices.
13,103 VENNER & GRIESBACH. Automatic electric switches.*
13,124 B.T.-H. Co. (G.E. Co., U.S.) Arc lamp electrodes.

June 1, 1911.

13,142 LONGFORD & ASTON. Trimming magneto contacts.
13,177 STOBIE & DAVONPORT. Electric metallurgical furnaces.
13,213 MILNE. Electric wiring of buildings.

June 2. 1911.

13,246 ELECTRIC & ORDNANCE ACCESSORIES Co., GARNER & COLLINS. Pole shoes of magneto-electric machines for ignition purposes in connection with internal combustion engines.
13,266 BAYLEY, jun., & WOOD. Electrical accumulators.
13,272 EARNSHAW. Life guard for use on tramcars and such like.
13,282 MARKS. (Gans & Goldschmidt Elektrizitäts Ges.m.b.H. and Martin Kaul, Germany.) Apparatus for effecting the automatic forming of metal filaments for electric incandescent lamps.
13,285 HUMMEL. Electric lighting of staircases.*
13,299 LAKE. (U.S. Light & Heating Co., U.S.) Batteries.*
13,315 COMPAGNIE POUR LA FABRICATION DES COMPTEURS ET MATERIEL D'USINES A GAZ. Electric current limiting apparatus. (Convention date, 11/11/10, France.)*
13,335 ELEKTROCHEMISCHE WERKE G.M.B.H. & ROTHE. Producing disc-like flaming arcs for carrying out gas reactions. (Convention date, 8/7/10, Germany.)*
13,338 CREESE & ARON. Electrically operating time-indicating devices.
13,341 GRAEBE & LEHRBACH. Switch for electric illuminating devices.*

June 3, 1911

13,362 NISBET. Electrical machines.
13,403 BRADBURY. Electric resistance furnaces.

June 6, 1911.

13,430 PERRY. Wind power electric storage installation or apparatus.
13,450 TURNBULL, jun., & HOLMES. Regulating the voltage of electric generators.
13,469 TURNER & WILKINSON. Controlling apparatus for electric motors.
13,477 HIRST & ANGOLD. Automatic regulators for dynamo-electric machines.
13,483 VIGNEAULT & HEBERT. Magnetic compound.*
13,490 LUY. Magneto-electric lamp apparatus.*
13,492 KRYSHTOFOVICH. Transmission of electric power.
13,509 TWIGGER. Holders for shades or globes of electric and other lamps.
13,522 ALHORN. Transformers for continuous current.*
13,524 SCHMIDT. Spark plugs. (Convention date, 9/6/10, United States.)*
13,525 RICHARDSON. Manufacture of filaments for electric incandescent lamps.
13,561 TATE & MONKHOUSE. Arc lamps.
13,570 B.T.-H. Co. & POLLOCK. Regulators for dynamo-electric machines.
13,571 B.T.-H. Co. & WEDMORE. Electro-magnets.
13,573 BLEICHERT & BLEICHERT. Remote controlling means for electric trolleys.*
13,574 BLEICHERT & BLEICHERT. Remote controlling apparatus for electrically actuated travelling winches and the like.*

June 7, 1911.

13,601 ROOSE & FINLAY. Intercommunication telephone systems with secrecy.
13,604 FERRA. Thermo-electric generators.
13,605 FERRA. Generation of electric current.
13,615 RICHARDSON. Manufacture of filaments for electric incandescent lamps.*
13,623. SCHAEFFER. Air propeller driven by electric motor. (Convention date, 2/7/10, Germany.)*
13,641 STEINBERGER. Telephone mouthpieces. (Convention date, 13/6/10, U.S.)*
13,647 NETTENSTROM. Power transmission.*
13,648 STILLE. Electrical switch or operating devices. (Convention date, 20/7/10, Germany.)*
13,650 B.T.-H. Co. & YOUNG. Regulation of electric generators driven at varying speeds.

June 8, 1911.

13,662 HALL. Timing apparatus for magneto-electric ignition.
13,685 CODD. Electro-mechanical cut-outs.
13,705 BUSCH. Magneto-electric ignition machines. (Convention date, 27/8/10, Germany.)*
13,707 SIEMENS BROS. & Co. (Siemens & Halske Akt.-Ges., Germany.) Electrical measuring instruments of the dynamometer type.*
13,715 SUCHTING & OLOFF. Thermo-electric batteries.*

June 9, 1911.

13,750 HOWARD. Metallic armouring for insulated electric cables.
13,758 SMITH. Portable electric battery lamps.
13,782 PAPE. Manufacture of electric accumulator electrodes and means for use therein.
13,808 RODECK. Electro-deposition of metals. (Convention date, 10/6/10, Austria.)*
13,817 GEBRUDER SIEMENS & Co. Electric arc lamp electrodes. (Convention date, 29/6/10, Germany.)*
13,830 DUNNING. Electric circuit controlling devices. (Convention date, 10/6/10, U.S.)*

June 10, 1911.

13,877 SIEMENS SCHUCKERTWERKE GES. Speed regulation of polyphase series motors. (Convention date, 10/6/10, Germany.)*
13,884 ROSENBERG. Microphones.
13,885 ROSENBERG. Supporting a telephone receiver or similar instrument in contact with the ear.
13,886 THOMAS. Detachable coupling for electrical connections.
13,887 GRAHAM. Telephone exchange switchboards and arrangements.*
13,893 GRAFTON. Electric lighting of motor road vehicles and the like.

June 12, 1911.

13,905 SAYER. Maintaining constant the speed of a dynamo or other machine driven from a motor having variable speed.
13,948 BANN. Telephone receiver holders.*
13,968 SCHIESSLER. Electric inductive couplings. (Divided application on 24,696/10. 24/10.)*
13,970 NICHOLSON & NICHOLSON. Combined track and trolley switch operating mechanisms.*
13,984 ORLING & ORLING'S TELEGRAPH INSTRUMENTS SYND. Relay device.
14,987 B.T.-H. Co. (A.E.G., Germany.) Insulated electric conductors.*

June 13, 1911.

14,005 PRESTON. Regulating the power of an electro-magnet by either increasing or decreasing the number of turns in the windings.
14,008 GAMBRELL & GAMBRELL. Electrical condenser charge and discharge keys and the like.

Digitized by Google

14,032 BARBOUR. Electric motor starters.
14,034 PHILLIPS & A. C. COSSOR. Pivot and moving system for electrical and magnetic measurement and detection.
14,050 HUIZER. Primary electric batteries.*

June 14, 1911.

14,092 FEHR. Automatically actuating the track points of electric railways and the like.
14,096 MILLS. Tramcar trolley-heads.
14,110 TUCKER. Electrical wall sockets and the like.*
14,123 ARON. Electrically operated time-indicating systems.
14,127 SIEMENS BROS. DYNAMO WORKS. (Siemens-Schuckertwerke G.m.b.H., Germany.) Arc Lamps.*
14,144 SIEMENS BROS. & Co. (Siemens & Halske Akt.-Ges., Germany.) Calling circuit arrangements for automatic and semi-automatic telephone exchanges.*
14,148 AUTOMATIC ELECTRIC BLOCK SIGNALLING CO. & BROUSSON. Electrically-operated signals for railways.

June 15, 1911.

14,175 ROTTENBURG. Electrical servo and telemotors, and their modes of application.
14,179 DAY. Electrical contact making devices.
14,183 HEATH & HARRISON. Globe or shade holders.
14,222 MIETH. Electrically-heated vessel.*
14,239 SOC. ANON. ELECTROMETALLURGIQUE (PROCEDES PAUL GIROD). Refining steel. (Addition to 26,598/09. Convention date, 15/6/10, France.)*

June 16, 1911.

14,274 ECCLES. Instruments for the measurement of electric currents and voltages.
14,276 LEACH. Miners' electric safety lamp.
14,303 BEY. Electric lamp holders for electrically-illuminated signs and devices.
14,360 VAUGHAN. Magneto-generating machines.

June 17, 1911.

14,380 LEVERMORE & MORRIS. Facilitating the connection of the trolleys attached to road cars, tramcars, and the like with the overhead wires.
14,410 ARON & DORMANN. Electrically-operated time-indicating devices.
14,432 SIEMENS SCHUCKERTWERKE G.M.B.H. Automatic regulators for electric circuits. (Convention date, 17/6/10, Germany.)*

SPECIFICATIONS PUBLISHED.

1910 SPECIFICATIONS.

1,893 SIMMS. Distributors for electric accumulator ignition gear. (25/7/10.)
10,717 HARRIS. Electric detonators for blasting. (Patent of addition not granted.)
11,336 HEATHER. Increasing the safety of the operations of hoisting and lowering with induction motors.
13,224 ADAMS MFG. CO. ((Cutler Hammer Mfg. Co.). Starting devices for electric motors.
13,325 ADAMS MFG. CO. (Cutler Hammer Mfg. Co.). Controllers for electric motors.
13,335 ADAMS MFG. CO. (Cutler Hammer Mfg. Co.) Starting devices for electric motors.
13,453 RANKIN. Electric controlling and regulating apparatus.
13,476 MCGEOCH & MCGEOCH & CO. Electric switches.
13,694 B.T.-H. CO. (G.E. CO.). Electrical transformers. (Addition to 13,278/04.)
14,380 PRICE. Prevention of sparking in the control of electric circuits.
14,391 AKT.-GES. BROWN, BOVERI ET CIE. Alternating current commutator machinery (17/6/09.)
14,429 HALLIWELL & JEREMIAH. Locking electric incandescent lamps to their holders.
15,137 HERING. Electric furnaces. (6/7/09.)
16,017 SHAW & GREEN. Detachable power handle for controllers on electric cars, cranes and the like.
16,485 LITTLER. Quick break switch on circuit breaker applicable to arc lamp and other electrical circuits.
17,873 UPTON. Means and appliances for removing and replacing electric light or like bulbs in their sockets.
18,359 DICKSON. Electric switches and signs.
19,359 B.T.-H. CO. (G.E. CO.). Alternating electric current motors.
19,532 ESSER & HODGKINSON. Electric lighting of motor cars, cycles, and other vehicles.
19,795 CITY OF LONDON ELECTRIC LIGHTING CO. & PEARD. Supporting and raising and lowering lamps.
21,041 B.T.-H. CO. (G.E. Co., U.S.) Electric voltage regulation.
21,157 GILBERT ARC LAMP CO. & DOWDELL. Electrodes for arc lamps.
21,522 SPEIGHT & WALMSLEY. Hangers or ears for overhead electric wires or conductors.
21,922 DUNNE. Secondary Batteries.
22,013 SIEMENS & HALSKE AKT.-GES. Telephone exchange circuits. (29/1/10.)
22,642 WILLIAMSON. Fire brigade and like electric alarms.
22,852 WESTINGHOUSE METALLFADEN GLUHLAMPENFABRIK GES. Metallic filament electric lamps. (6/10/09.)
22,959 NEUHOLD. Automatic telephone systems. (3/9/10.)
24,216 MAYES. Electric incandescent lamp cap.
24,808 THOMPSON. (Wirth, Bock & Knauss.) Apparatus for stopping and returning to the initial position electrically-operated mechanisms.
24,818 NEPLE. Inclinable electric lamp supports. (26/10/09.)
25,205 BAUER. Producing X-ray pictures and appliances there for.
25,502 AITKEN & BRITISH INSULATED & HELSBY CABLES. Telephone switchboards.
27,174 SOC. VEDOVELLI, PRIESTLEY & CIE. Suspension chain for high pressure electric transmission wires. (5/4/10.)
27,206 SIEMENS & HALSKE AKT.-GES. Automatic telephone circuits. (20/11/09.)
27,223 GARDNER & FERGUSON. Apparatus for causing electrical impulses for transmission to a distance.
27,860 SIEMENS & HALSKE AKT.-GES. Telephone exchanges with automatic call distributors. (9/12/09.)
28,657 Dr. PAUL MEYER AKT.-GES. & KUHNEL. Mercury contact electric switches.
28,834 RASMUSSEN. Composition for the use of electric insulating and other commercial purposes.
29,463 GRISSINGER. Automatic electric heat control. (22/12/09.)
29,506 SCHMIDT. Arc lamps. (20/12/09.)
29,700 SMITH & KAATZ. Incandescent lamp regulator.
29,726 CROMPTON & CO. & BURGE. Converting electric currents for supplying electric motors.

1911 SPECIFICATIONS.

132 LUDECKE & IMPERIAL LAMP WORKS (BRADDOWN) LTD. Manufacture of metal filaments for electric lamps
741 MOUL. (Kortine.) Arc lamps.
996 JULIUS PINTSCH AKT.-GES. Electric lighting plant for railway trains. (17/1/10.)
1,037 PENROSE. Electrical switches.
1,056 LANDIS & GYR. Electricity meters.
2,242 LANGE. Aerial conducting structures for wireless telegraphy and telephony. (2/2/10.)
2,259 MEHNE. Time switches for controlling electric circuits and for turning on and off gas lights. (Patent of addition to 14,052/09.)
2,520 TRAUS. Electric lamp switches. (4/2/10.)
2,594 SIEMENS BROS. DYNAMO WORKS & BOLTON. Electric switches.
3,251 PAULING. Electric furnace for treating gases.
3,705 SUN ELECTRICAL CO., RAWLINGS & SWEETSER. Electric switches.
3,747 SEFTON-JONES. (Oesterreichische Daimler-Motoren Ges.). Supports for electric conductors or rail-less track systems. (Divided application on 27,798/10. 29/11.)
3,947 GIRARDEAU. Radio-telegraphic plant. (1/12/10.)
4,077 GAMPER. Facilitating the packing of magnetic material.
5,248 Dr. ERICH F. HUTH GES. & HIRSCH. Apparatus for use in wireless telegraphy. (3/8/10.)
6,336 KORTING & MATHIESEN AKT.-GES. Alternating-current arc lamps. (29/3/10.)
6,783 KORTING & MATHIESON AKT.-GES. Alternating-current arc lamps. (29/3/10.)
9,815 SCHALLER. Electric incandescent lamp. (22/4/10.)
10,792 SCHOTT & GEN. Electrolytically measuring electricity. (23/5/10.)

COMPANIES' MEETINGS AND REPORTS.

Anglo-American Telegraph Co. (Ltd.)

The half-yearly meeting was held on Friday, Mr. F. A. BEVAN presiding.

The SECRETARY (Mr. T. H. Wells) read the notice convening the meeting and the auditors' report.

The CHAIRMAN then said this was the half-yearly meeting at which all the directors had to do was to put before the shareholders their report and statement of accounts for the past half-year. But there were matters of very great interest and importance alluded to in that report, and therefore he should go into those matters which had occupied for so long a time the attention of the board, and which had been the subject of a great deal of comment in the Press, and of talk among the shareholders. Before doing so he would remark upon the great falling-off that there had been in the receipts for the past half-year as compared with the corresponding half-year. The half-year's receipts, compared with those of the corresponding half-year, had declined to the extent of £37,000. Owing to the Western Union Co. having come to the conclusion that under the Sherman Trust Act the pooling agreement of 1882 was invalid, from March 1 last they had ceased to receive from the Western Union Co. the amount of traffic that they had hitherto been in the habit of receiving. They had therefore since that date ceased to hand over this traffic to the Anglo-American Co., and thus they had earned £37,000 less. That showed the immense importance of keeping on the best of terms with the Western Union. A great deal more than half the Company's traffic arose on the other side of the Atlantic, and it was in the power of the Western Union with their enormous ramifications throughout the Continent, to dispose of that traffic as they pleased. So long as there was a pooling agreement it did not matter whether the traffic came by the Anglo-American line or by the Western Union, but directly the pooling agreement ceased to take effect, the Western Union, having in the meantime laid a further cable which enabled them to carry the traffic they had not been able to do before, took a larger proportion for themselves. For some months before this occurred the Anglo-American Co. had been negotiating with the Western Union for a new agreement. He hoped that in a few days the arrangements would be complete, and then the shareholders would be specially called together to consider it. The principal terms were that the Western Union should take the lease of the Anglo-American Co.'s cables for 99 years. That involved the purchase by the Anglo-American Co. of the new cable laid down by the Western Union Co. That would absorb the greater part of their renewal fund—at least £700,000, or perhaps a little more. The Western Union were to give them a guarantee of 3¼ per cent. on their ordinary stock, amounting to £262,500, payable quarterly, and as the preferred stockholders took 6 per cent. that would leave 1¼ per cent. on the deferred stock. This meant that for 99 years the Western Union, which had an enormous capital, were bound to keep up their payment to the Anglo Co. of £262,500 a year. They were to maintain the Anglo-American Co.'s renewal fund in just the same way as they had themselves maintained it. They were to set aside £20,000 a year, and the interest upon the securities in which the fund was invested. The management would be in their hands, but a small board would be retained who would act really as trustees for the Anglo-American shareholders. The Western Union were to maintain the cables and all the Company's property so that in the very unlikely case of the agreement having to be broken through matters over which they had no control, their property would be restored to them in the same condition as far as possible as it was when they handed it over to the Western Union. The Board believed that in the interest of the shareholders it was very desirable that the agreement should be entered into. It must be remembered that the larger portion of the business of the Company originated in the United States, and not on this side of the Atlantic, and therefore if the Anglo-American Co. were to continue to have their fair proportion they must enter into some such arrangement as was now proposed. The security was as good as it could possibly be. Instead of having stock which was continually fluctuating according to the prospects of the half-year, the shareholders would have what he might call a gilt-edged security with an absolute fixed rate of interest guaranteed by one of the most powerful companies in the United States. When the Western Union first proposed this agreement they stated that they wished to make certain improvements with regard to the traffic arrangements. They wanted to have deferred messages at a cheaper rate. The board saw very soon that the company might suffer loss through this arrangement. Now the Western Union could make what arrangements they pleased. Whatever they did would be at their own risk. Whatever their tariff they were bound to give the Anglo-American Co. the £262,500 a year. Those were the principal reasons why the directors, after the most careful consideration, had thought it well to enter into this arrangement. It could not be carried through without the shareholders' consent. They would have the opportunity of considering, discussing, and voting upon it. He hoped the day was not far distant when the board would summon the shareholders to a special meeting for the consideration of this matter. He could not say that it was altogether what they liked, the surrendering of the management to the hands of the American Co. Perhaps it was only a sentimental question. If they could have gone on he did not think they would have moved in that connection, but the pressure came from the other side. They had to consider not sentiment but the interests of the shareholders. He then moved the adoption of the report and accounts.

Sir GERALD FITZGERALD seconded the motion, which, after a few brief complimentary observations from shareholders, was adopted, and the proceedings terminated.

BULAWAYO WATERWORKS & ELECTRIC LIGHTING CO. (LTD.)—The directors' report for the year ended Dec. 31, 1910, states that gross profit from sale of electric current was £2,777, decrease £961, compared with the previous year. On the company's whole undertaking there is a total of £9,009 to the debit of profit and loss account. The sum now standing to reserve on depreciation and renewal account is £44,525. The decrease in revenue from the sale of electric current was entirely due to the general use of metallic filament lamps by private consumers, and their substitution for carbon lamps in the street lighting, but during the present year there has been a very great expansion of trade.

CROMPTON & CO. (LTD.)—At the meeting on Monday the Chairman Mr. J. Trotter, moved the adoption of the directors' report (abstracted in our last issue). He said the result of the year's working, after paying all charges, was a loss of £14,000, as compared with £20,000 last year. If prices remain as they are it only required a larger turnover to earn a satisfactory profit. There was a distinct improvement in the outlook of the electrical industry, and they were devoting themselves to improving the output. The report was adopted.

GREAT NORTHERN & CITY RAILWAY CO.—The directors' report for the half-year to June 30 states that the total revenue was £41,844. 13s. 7d. and cost of working £20,157. 13s. (48·17 per cent.). Traffic receipts were £39,864 (against £37,911 in the corresponding half of 1910). Net revenue was £21,687. 0s. 7d., which was insufficient to meet the company's fixed charges for the half-year, and £1,110. 12s. 10d., has been provided from outside sources. The number of passengers for the six months including season ticket holders, was 6,323,045 against 5,966,114 for the corresponding period last year. 2,524 local season tickets were issued, against 2,539. The number of three-route season ticket holders using the company's line during the past half-year was 3,166, against 2,728.

At the meeting on Wednesday the chairman (the Earl of Lauderdale) said that the cost of working had been at the rate of 48·18 per cent., against 50·12 for the same period of last year and 51·09 for the half-year ended Dec. 31 last. The net revenue increased by £1,903, and although that did not enable the Board to meet the entire fixed charges, yet it reduced the deficiency from £3,163 to £1,110 for the half-year just ended. The company seemed to be on the up grade. The recovery was naturally slow, but it was satisfactory to note that in the face of the keenest competition they were gradually, but he hoped surely, regaining the traffic they had lost. That they had had this half-year to rely upon outside assistance for but a comparatively small sum of money was a satisfactory feature in the position, and should they be able, as the directors believed would be the case, to maintain the steady increase in the company's takings, the day should not be far distant when it would again be quite independent.

LONDON, BRIGHTON & SOUTH COAST RAILWAY CO.—At the meeting on Wednesday Mr. C. C. Macrae, who presided, said that, comparing the June half-years, it was only in the years 1903 and 1904, when the present tramway competition was not fully developed, that the number of 27,000,000 passengers carried during that half-year was exceeded. From 1904 there was a gradual diminution in the numbers of their passengers until the opening of electrical services on the South London Railway at the end of 1909. Since then there had been a rapid increase, and they had not only regained the whole of the number lost on that section of railway, but during the last six months they had carried more passengers over it than they did prior to the establishment of the electric trams. He thought that showed very conclusively that electric traction on a railway could more than hold its own in competition with electric trams, and that the policy of the board with regard to electrification had been justified. The electrical services between Victoria and the Crystal Palace had only been running since May 12, but the result was equally satisfactory. At the end of this year, when they hoped similar services would be established between London Bridge and the Crystal Palace, they expected to attain even better results. It had not been practicable as yet to open these services because the contractors for the supply of energy had not been in a position to give the quantity required. They were, however, pushing on as quickly as possible with the works necessary for that supply, and they would make use of it as soon as they could get it. The electrical services were also quite satisfactory from the revenue point of view, and the additional receipts derived from them represented nearly 30 per cent. of the total increase of passenger receipts. Second-class tickets had been abolished on June 1, because of the introduction of electric traction on the line.

LONDON ELECTRIC RAILWAY CO.—Capital expenditure during the half-year ended June 30 amounted to £47,222. 10s. 7d. Gross receipts amounted to £392,817. 8s. 9d., an increase of £27,193. 2s. 3d. over the corresponding half of last year. Working expenses were £174,919. 11s. 1d., an increase of £7,699. 4s. 2d. After providing for interest and rents, and reserving £7,500 for contingencies and renewals, there remains £124,156. 3s. 7d. available for dividends, and the directors recommend that a dividend at the rate of 4 per cent. be declared on the preference stock, and at the rate of 1 per cent. on the ordinary shares, leaving £14,516. 9s. 7d. to be carried forward. The train mileage was 2,728,961, a decrease of 159,470, and the car-mileage was 9,284,870, an increase of 777,514. 52,548,384 passengers were carried, against 46,665,279 in the December and 50,045,140 in the June half-year of 1910. The company propose to proceed with the construction of the Charing Cross and Paddington extensions at an early date.

METROPOLITAN DISTRICT RAILWAY CO.—Capital expenditure during the half-year ended June 30 was £88,668. 14s. 5d. Gross receipts were £327,170, increase £27,124 over the corresponding half of last year. Working expenses were £152,741, increase £9,410. After providing for interest and other charges and setting aside £10,000 as reserve for renewals, the credit balance is £82,991. 18s. 7d., and the directors recommend that the full dividend be declared on the 4 per cent. guaranteed stock and on the 4½ per cent. first preference stock. The number of passengers carried (including workmen and season ticket holders) was 40,539,464, an increase of 4,359,156; the number of passengers carried at workmen's fares was 7,050,800, increase 404,268; average receipt per passenger 1·81d., against 1·86d.; train mileage 1,743,068, against 1,666,350; and car-mileage 7,107,134, against 6,646,998. 31 new carriages have been put in service during the half-year; 20 carriages remain to be delivered by the builders, and an order has been placed for 14 additional carriages.

MEXICAN LIGHT & POWER CO. (LTD.)—The report for 1910 states that during the past year the business has shown constant and satisfactory increases. Net revenue in gold for the year, after paying all expenses and fixed charges, was $1,456,612, and $149,385 from 1909 and $163,004 set aside from profits of 1909 to provide for the accrued dividend make $1,769,002. The directors have paid during the year $860,150 in dividends. The balance to profit and loss account is $745,848 and the reserve account remains at $377,883. The purchase of the business and undertaking of the Compania Electrica e Irrigadora en el Estado de Hidalgo, S.A., was completed during the year, and the results justify the action of the board in acquiring it. A transmission line has been constructed from the line of the Mexican Light & Power Co. to the lines of the Pachuca Light & Power Co. at Pachuca, and the Pachuca Company is taking 9,500 H.P., which it is selling in addition to the regular output from its own plants.

MEXICO TRAMWAYS CO.—The report for 1910 states that the net revenue in gold after paying all expenses and fixed charges, was $1,417,303, added to $416,344, balance from 1909, making $1,833,647. During the year dividends absorbed $931,581, leaving $894,066, out of which $250,000 have been added to reserve, and $644,066 have been carried forward. On Dec. 31, 1910, the system consisted of 179 miles of single track, of which 158 miles were operated by electricity and 21 by mules, the electric track mileage having been increased by 13 miles and the mule track reduced by five.

NEW GENERAL TRACTION CO. (LTD.)—The revenue for the year ended March 31 was £22,656, against £19,482 in 1910. The profit was £3,674, reducing the balance of loss to £21,631. Coventry Corporation have given notice of their intention to acquire the Coventry Electric Tramways.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES, &c.

NEW COMPANIES.

ANGLO-BRAZILIAN POWER AND SHIPPING CORPN. (LTD.) (116,742.)—Reg. July 11, capital £300,000 in £1 shares, to promote, purchase, apply for or otherwise acquire, contract for and hold, construct, equip, maintain, work, lease, or let any works in South America or elsewhere, and in particular factories, tramways, railways, ropeways, telegraphs and telephones (elsewhere than in the U.K.), cables, harbours, elevators, sidings, reservoirs, engineering, hydraulic and electric power and light works, &c., and to adopt an agreement with Horacio P. Vieira, relating to the sale of some land in the State of Parana, Brazil, with water rights. Purchase consideration, £270,000 in shares and £30,000 in cash. The British South American Financial Corpn. are to receive £100,000 shares and J. P. Nelson is to receive £5,000 shares from the vendor for services rendered in connection with the promotion of the company. First directors: Horacio P. Vieira, J. P. Nelson, and J. Wolstenholme. Reg. office, 4, London-wall Buildings, E.C.

ANGLO-FRENCH WIRELESS CO. (LTD.) (117,056)—Reg. July 29, capital £50,000 in £1 shares, to carry on the business of electrical and mechanical engineers and contractors, suppliers of electricity, manufacturers of and dealers in railway, tramways, electric and other apparatus, &c., to acquire certain inventions, patents, rights, privileges and other property relating to wireless telegraphy and telephony, and to adopt an agreement with Compagnie Generale Radiotelegraphique. Private company. First directors are M. Sins and M. Trouchon.

LONDON & MEXICO CONCESSIONS SYND. (LTD.) (116,939)—Reg. July 21, capital £20,000 in 18,000 £1 ordinary shares and 40,000 deferred shares of 1s. each, to acquire powers for construction and operation of railways, tramways, telegraphs, telephones, harbours, quays, docks, and irrigation, gas, electric light and power and other public works, &c., in relation to Mexico, Great Britain, Africa, Australia, Canada any British colony or dependency, North and South America, Japan, China and Europe. Private company. Reg. office: 3, Lombard-street, London, E.C.

PROVINCIAL ELECTRICAL CO. (LTD.) (116,972)—Reg. July 24, capital £250 in £1 shares, to carry on the business of electricians, electrical engineers, manufacturers of and dealers in apparatus and plant for electric lighting, telephones, telegraphs, or for producing power by means of gas, electricity, hydraulic, steam and other means, &c. Private company. First directors: W. H. Buxton, W. H. Bagley and F. E. Butler.

THOMAS THORP CO. (LTD.) (116,961).—Reg. July 22, capital £10,000 in £1 shares (3,000 preference), to take over the business carried on at Victoria Works, Besses-o'-th'-Barn, Whitefield, Lancs., as "Thomas Thorp & Co." and to carry on the business of manufacturers of and

Digitized by Google

dealers in gas, electric and water meters and scientific instruments, electricians, electrical, mechanical and civil engineers, &c. Private company. First directors: T. Thorp, F. Thorp and H. T. Thorp.

WILSON APPARATUS CO. (LTD.) (116,761.)—Reg. July 11, capital £900 in £1 shares (300 "A" and 600 "B") to carry on the business of electricians, engineers, manufacturers of and dealers in instruments and apparatus used in connection with the generation, supply, accumulation and employment of electricity, &c., and to adopt an agreement with F. W. Wright, E. Wilson and W. H. Wilson. Private company.

STATUTORY RETURNS.

BOURNEMOUTH & POOLE ELECTRICITY SUPPLY CO. (LTD.)—Return to March 30, gives capital as £500,000 in 25,000 ordinary, 7,500 4½ per cent. preference and 17,500 6 per cent. second preference shares of £10 each. 15,000 ordinary, 7,500 4½ per cent. preference and 15,000 6 per cent. second preference shares taken up. £375,000 paid. Mortgages and charges: £187,500.

BRIDGWATER & DISTRICT ELECTRIC SUPPLY & TRACTION CO. (LTD.)—According to return to May 4, capital is £20,000 in £1 shares (5,000 preference). 12,899 ordinary and 525 preference shares taken up. £4,552 paid on 4,017 ordinary and 525 preference, including £10 on 100 forfeited shares. £8,882 considered as paid on 8,882 ordinary shares. Mortgages and charges £12,000.

BROMPTON & KENSINGTON ELECTRICITY SUPPLY CO. (LTD.)—Return dated March 30, filed April 28, 1911. Capital £300,000 in £5 shares (9,551 preference). 9,551 preference and 30,449 ordinary shares taken up. £5 per share called up on 9,551 preference and 29,449 ordinary. £195,000 paid. £5,000 considered as paid on 1,000 ordinary shares. Mortgages and charges: Nil.

CALCUTTA TRAMWAYS CO. (LTD.)—Return dated May 3 shows capital £1,400,000 in 140,000 ordinary and 140,000 preference shares of £5 each. 137,610 ordinary and 47,295 preference shares taken up. £2 per share called up on 4,400 ordinary, £2. 10s. per share on 8,000 ordinary, £3. 10s. per share on 22,000 ordinary, £5 per share on 79,430 ordinary and £5 per share on 47,295 preference. 23,780 ordinary considered as fully paid. £3 per share considered as paid on 4,400 ordinary, £2. 10s. per share on 8,000 ordinary and £1. 10s. per share on 22,000 ordinary. Mortgages and charges: £350,000.

CAMBORNE ELECTRICITY SUPPLY CO. (LTD.)—Return dated June 14, filed July 3, 1911. Capital £10,000 in £1 shares. 607 shares taken up. £1 per share called up. £605 paid, leaving £2 in arrears. Mortgages and charges: Nil.

CEDES ELECTRIC TRACTION (LTD.)—Return dated July 11, filed July 15, 1911. Capital £20,000 in £1 shares. 3,000 shares taken up. £3,000 paid. Mortgages and charges: Nil.

EASTERN TELEGRAPH CO. (LTD.)—Return dated May 31 shows capital £6,000,000 in £4,000,000 ordinary stock and £2,000,000 preferred stock. All stock taken up. £6,000,000 paid. Mortgages and charges: £1,896,705.

MORTGAGES AND CHARGES.

BURFORD ELECTRIC LIGHT & POWER CO. (LTD.)—Particulars of £1,500 debentures, created June 10 have been filed, the whole amount being issued. Property charged: Company's undertaking and property, present and future, including uncalled capital. No trustees.

CUTTING BROS (LTD.)—A Memorandum of satisfaction in full on Nov. 10, 1910, of debentures dated June 20th, 1904, securing £4,000, has been filed.

LAMPLOUGH & SON (LTD.)—An agreement, and a debenture issued pursuant thereto, both dated June 29, to secure £3,000, charged on Albany Works, Willesden; benefit of a licence, and the company's undertaking and property, present and future, including uncalled capital. Holders: London Steel Castings Co.

CITY NOTES.

MEMORANDA (Aug. 3).—Bank rate 3 per cent. (March 9, 1911.) Price of silver, 24 7/16d. per oz. Consols 77⅛—78⅛ for money; 78—78⅛ for account. Consols Pay Day, Sept. 1; Stock and Shares Continuation Days, Aug. 14 and 29; Ticket Days, Aug. 15 and 30; Pay Days, Aug. 16 and 31; Mining Shares Carry Over Day, Aug. 11.

PRICES OF METALS (London).—*Copper*, cash, 56⅜; three months, 56⅞. *Lead*, English, 14¼—14½; Foreign, 14—14¼. *Spelter*, 25¾—26. *Tin*, English, 193½—195½; Foreign, cash, 192½; three months, 188¾. *Iron*, Cleveland, cash, 46/9, three months, 47/7.

BRISTOL TRAMWAYS & CARRIAGE CO. (LTD.)—The directors have declared an interim dividend at the rate for 4 per cent. for the half-year ended June 30.

BRITISH ELECTRIC TRACTION CO. (LTD.)—The following circular letter has been addressed to the shareholders:—

As intimated in the last annual report, the directors have for some time past had the question of a re-organisation of capital in all its bearings under careful consideration, and I enclose a memorandum containing their proposals. [A lengthy memorandum accompanies the letter.]

The chief reasons for the proposals briefly are:—

(*a*) Depreciation of some of the assets has taken place, as has been explained by the directors and by the Company's auditors in their reports to the shareholders.

(*b*) The present profits are insufficient to pay the full cumulative dividend on the preference shares, and arrears are accumulating in front of the ordinary shareholders.

(*c*) A reduction of capital, which would fall on both the preference and ordinary shareholders, has been suggested as a way of meeting the depreciation of assets, and of adjusting the rights of the two classes of shares.

(*d*) For the reasons stated in the memorandum, however, the directors do not consider that a reduction of capital is in the best interests of the shareholders.

The directors therefore recommend a re-arrangement, not a reduction, of capital, and they propose to continue to deal with depreciation of assets in the manner described in the memorandum and in their previous reports. By the proposed re-arrangement of capital, the preference shareholders obtain an advantage in regard to priority of capital, and waive part of their rights to future distribution of profits. The holders of the ordinary shares have their prospect of dividend improved, and waive part of their rights as to capital. The re-arrangement necessarily contains some elements of a compromise, and has presented many difficulties in the equitable adjustment of its details. The directors, however, are satisfied that the proposals are just and fair to both classes of shareholders, and they unanimously recommend them for adoption. The memorandum requires careful perusal in its entirety, and in order to allow the shareholders time to consider the matter, the directors propose to defer holding the necessary extraordinary general meetings until October. Meanwhile any shareholder who so desires may obtain further explanation or information by letter or by personal application at the offices of the Company. CHAS. H. DADE, Secretary.

Electrical Federation Offices, Kingsway,
London, W.C., July 31.

BROMPTON & KENSINGTON ELECTRICITY SUPPLY CO. (LTD.)—The directors have declared an interim dividend of 9 per cent. (4s. 6d. per share), less tax, on the ordinary shares for the half-year to June 30.

CANADA.—Amongst the companies recently incorporated by Acts of the Quebec Provincial Legislature are the Montreal Tramways Co. (capital £4,110,000), to acquire existing electric railway undertakings and to construct tramways in Montreal city: and the Montreal & South-Western Railway & Power Co. (capital £411,000).

The "Financial News" says it is understood that with the transfer of the Toronto Electric Light Co. to the Mackenzie and Mann interests, on Aug. 1, there was to be a change in the management of the company. Mr. H. H. Macrae is, it is said, to retire, and it is likely Mr. R. J. Fleming (manager of the Toronto Railway Co. and the Electrical Development Co.) will be asked to direct the affairs of the Toronto Electric Light Co. This would place Mr. Fleming in control of all the Mackenzie and Mann electrical enterprises that furnish light and power to Toronto.

CHARING CROSS, WEST END & CITY ELECTRICITY SUPPLY CO. (LTD.)—The directors have decided to pay an interim dividend at the rate of 5 per cent. on the ordinary shares of the West End undertaking.

KENSINGTON & KNIGHTSBRIDGE ELECTRIC LIGHTING CO. (LTD.)—The directors announce an interim dividend of 4s. per share (at the rate of 8 per cent.), less tax on the ordinary shares for the past half-year.

MADRAS ELECTRIC TRAMWAYS, 1904 (LTD.)—This company's traffic receipts for the fortnight ended July 31 were R.23,607 (increase R.2,858). The aggregate from Jan. 1 was R.307,946 (increase R.25,749).

METROPOLITAN ELECTRIC SUPPLY CO. (LTD.)—An interim dividend at the rate of 4 per cent. for the half-year ended June 30 is payable on 10th inst.

RIO DE JANEIRO TRAMWAY, LIGHT & POWER CO. (LTD.)—The gross earnings of this company during June were £220,267 (increase £25,936). The aggregate from Jan. 1 is £1,036,179 (increase £218,844).

SCANDINAVIAN POWER SCHEME.—It is stated that negotiations are proceeding between German, English and Scandinavian financial interests for the amalgamation of a number of Norwegian and Swedish power companies in a new undertaking to be called the Hydraulic Power & Smelting Corpn., which will carry on zinc smelting and refining at Thallhätta and Sarpsborg, and the hydraulic power station at the mouth of the Tysse on the Hardanger Fjord, now generating 57,000 H.P., and to be ultimately increased to 126,000 H.P. In Germany the Siemens-Schuckert Werke, the A.E.G. and the Gesellschaft für Elektrische Unternehmungen are said to be financially interested in the scheme. The proposed capital is £1,000,000, with borrowing powers of the same amount.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have been asked to appoint a special settling day in and grant a quotation to a further issue of 37,900 £1 fully-paid ordinary shares of *Marconi's Wireless Telegraph Co. (Ltd.)*, to appoint a special settling day in a further issue of 74,362 7 per cent. £1 cumulative participating preference shares of the same company, and to allow 227,011 7 per cent. £1 cumulative participating preference shares of the same company to be quoted. The committee have also been asked to grant quotations to a further issue of £20,000 4½ per cent. 1st mortgage prior lien gold bonds of the *Montreal Water & Power Co.*, and partly paid scrip for £60,000 5 per cent. prior lien debentures of the *Torquay Tramways Co. (Ltd.)*

VICKERS (LTD.)—For the half-year ended June 30 interim dividends have been declared of 2½ per cent. (less tax) on the preferred stock and 1s. per share (tax free) on the ordinary shares.

WESTMINSTER ELECTRIC SUPPLY CORPN. (LTD.)—An interim dividend is announced for the half-year ended June 30 at the rate of 10 per cent. per annum (less tax), payable on Sept. 1 next.

NOTES.

The Joint Textile Committee.

THE publication of the names of members suggested for the Joint Committee to consider the uses of electricity for textile mill driving has already given rise to much comment, particularly among electrical manufacturers, who, singularly enough, have only two representatives on the Committee. Among the general and special duties of the Committee will be the examination of witnesses drawn from the manufacturing element, who will presumably give evidence on the work done by them, such evidence including data and technical information gained in the course of each particular firm's experience. From what we are able to gather in the textile districts, the manufacturers are competitively rather than co-operatively inclined. Consequently, it is conceivable that any one electrical manufacturer with a good textile connection will be disinclined to give away the details of his experience to his rivals. This diffidence will apply as much to a manufacturer sitting on the Committee as to one not doing so, and it is an attitude which can be readily understood. By the present constitution of the Committee electrical manufacturers need not be given seats, and certainly so small a number as two is totally inadequate to represent so large a body of interested electrical engineers. The situation will not be improved by the increase of this number, but rather by its decrease by the actual removal of the two representatives in question. The Committee will then have a clear road to collect its evidence in a manner which will give satisfaction to all the manufacturers alike. If some such step as the above is not taken, we fear that the work of the Joint Committee will suffer enormously in consequence.

Tramway Revenue.

ALTHOUGH tramway committees may sometimes be impressed by an increase in the traffic revenue per car-mile, it does not necessarily follow that such increase i always in the best interests of the undertaking, or most satisfactory to the passengers. This point is evidently appreciated by the Highways Committee of the London County Council, for in presenting the accounts of their electric tramways last week the Committee emphasised the fact that the decline in traffic revenue from 11·21d. to 11·0d. per car-mile during the past year did not necessarily indicate a decline in the prosperity of the undertaking; indeed, they mentioned that it had been found financially advantageous to increase the mileage run in certain instances, with a corresponding diminution in the revenue per car-mile. As to what is the most satisfactory figure for the revenue per car-mile must be left to each tramway manager to determine, since it depends, among other factors, upon the working expenses, the capital charges and the prospect of increased revenue with additional mileage in each case; 11d. per car-mile however, appears to be about the average figure reached, or favoured, on large undertakings in this country. It is worth noting, moreover, that at Blackburn, although a traffic revenue of 12·6d. per car-mile was recorded, a financial deficit was shown for the year ended March 31st last. Our detailed analysis elsewhere in this issue of the

Digitized by Google

past year's operation of the Manchester Corporation Tramways shows that the traffic revenue last year was 11·04d. as against 10·87d. in 1909–10. This is one of the most successful undertakings in this country, as may be judged from the fact that the ratepayers have benefited to the extent of over half a million pounds during the last 10 years; moreover, there was put aside out of last year's profits a sum of £86,250 for depreciation and reserve after contributing £75,000 to the rates. The financial success of a few of the largest tramway undertakings only emphasises the disparity between different undertakings. Thus, the Gloucester tramways, of which the annual accounts have recently come to hand, have required assistance from the rates to the extent of £2,925. As the total traffic revenue was only £14,966, and no allowance was made for depreciation, the ratepayers in this case have to pay heavily for the convenience of the cars.

Protecting High Tension Circuits.

When Mr. J. S. Peck read his paper some three years ago before the Institution of Electrical Engineers on apparatus for protecting high-tension lines against lightning and similar discharges, little had been done in this country in that direction, and at the present time we are dependent to a considerable extent on American experience. Valuable information on this subject has now been collected by the National Electric Light Association, and particulars of the report of a Committee of the Association and of the discussion thereon are given in our present issue. It appears that electrolytic arresters are coming into increasing favour and would be more largely employed if it were not for their high first cost and the trouble of charging. Their installation, however, is recommended except where other arresters are giving satisfaction. It is interesting to observe that Mr. P. M. Lincoln believes that better results can be obtained without arresters on overhead lines if suspension insulators and an earth wire are used. It may be noted that the Committee strongly advise the use of an overhead earth wire, and that this should be earthed at every support; a lightning rod placed above the earth wire is also recommended. It is extremely important that such lines should be rendered safe, and we think that those engineers who have studied the matter realise that a substantial continuous earth wire is the proper solution of the difficulty. Such a wire should be earthed at frequent intervals, though preferably not at every pole. It is useless to employ a wire that is not capable of carrying a reasonably heavy current, and the earth connections must not be of that haphazard variety which, we regret to say, is sometimes found.

International Telephone Lines.—The "Times" correspondent at Berne states that the Swiss Government has just announced that the Bill concerning the establishment of telephonic communication between Milan, Zurich, Basel, Frankfurt and Berlin has been passed by the Italian Parliament. The proposals for the new telephonic lines have still to be ratified by the authorities in Germany, Italy and Switzerland, but this is a mere matter of form. Tenders are to be invited for the construction of these new lines, and it is expected that the work will very soon begin; but as the shortest line between the different places must always be chosen, a new plan of the telephonic route has to be made. The railway lines are not to be followed, nor are the high roads, for it is intended that the new line shall be reserved exclusively for the telephone. The lines from Milan to Basel and from Milan to Basel and Frankfurt will probably pass through the Simplon and go via Lausanne, whence the shortest route will be taken to Basel. It is said that the establishment of these new telephonic communications will be one of the largest undertakings of the kind to be carried out in Europe next year.

Extension of the Anglo-French Telephone Service.—A short time ago the Post Office laid a new and improved telephone cable in the Straits of Dover (*see* The Electrician, Vol. LXVI., p. 375), and this has recently been connected to land lines from London and Paris, thereby providing increased and improved telephone facilities between the two capitals. By the extension of these circuits to provincial towns speech is rendered possible between places in England and France which could not previously so communicate with each other. In order to determine the extent of the increased range, experiments have recently been carried out by English and French officials from a number of provincial towns on this side of the Channel. Before the new cable was provided no town north of a line connecting the Humber and Mersey could communicate with Paris, but in the recent trials it was found possible to converse with the French capital from Newcastle-on-Tyne, Glasgow and Edinburgh, and finally trials were made from Aberdeen involving a circuit length of over 900 miles. With the best conditions of line and apparatus, commercial speech could be conducted from that place with Paris. These tests will enable the Post Office engineers to determine what other English towns can communicate with France, and it is hoped that a list of such towns will be published shortly. The increase in the range of telephonic speech has been brought about by means of the new telephone cable recently laid between England and France. This cable, it will be remembered, is fitted with loading coils which neutralise the disturbing effects on speech transmission introduced by the insulating material which must necessarily be employed when conductors are laid in water.

"Results of Experiments with Francis Turbines and Tangential (Pelton) Turbines."—In a Paper on this subject read at the recent meeting of the Institution of Mechanical Engineers at Zurich, Dr. F. Prásil stated that within the last 10 years the Francis turbine and the Pelton wheel in the most various forms of construction had quite taken the place of the old types, such as the Jonval and Girard turbines. Capacities as high as 16,000 H.P. in single units had now been reached. The Francis turbine was applied with success to falls of from 1 to 150 metres (3·3 ft. to 492 ft.); the Pelton wheel to falls from 40 to 950 metres (131 ft. to 3,116 ft.). In this progress was to be noted not only a steady improvement in the details of construction of the turbine, but also in the efficiency of the automatic governing and the safety-mechanism. Particularly in modern plants with long supply-pipes and conduits, with the severe specifications for high-standard reliability in the safety apparatus, these requirements made large claims upon the skill and ability of the engineers. The result had been, however, a large measure of success in the production of successful designs. In regard to efficiency, much further advance in the future was not to be expected; the problem of governing could still be considered as not yet completely solved, since there still appeared in view a series of applications which would influence the further development of this problem. The electrification of railways might be mentioned as one example. But the hope might well be expressed, considering the results already obtained, that with the help of the material and intellectual instruments now available, technical science would be able to find a satisfactory solution of these future, and perhaps of much more difficult, problems.

Arc Headlights for Electric Cars.—According to the "Electric Railway Journal" the new arc headlights developed by the General Electric Co. (U.S.A.) for electric cars embody a magnetite arc. The brilliant light given from these lamps when operated normally, insures units of high efficiency, while the low luminosity resulting with reversed polarity affords a most convenient means for dimming the glare of the lights. All the lamps are adjusted to operate in series on a 550-volt direct-current circuit, the voltage across the arc being 80 volts and the current 4 amperes. The headlights for cars operating on suburban tracks with many curves and intersecting roadways are equipped with parabolic reflectors of highly polished metal. They furnish a broad fan beam which illuminates the track directly from the head of the car and 50 ft. on each side to a distance of 1,200 ft. or 1,500 ft. On cars which operate only between towns the headlight illuminates the track to a distance of 2,000 ft., the beam being practically the width of the track alone. In these lamps the electrodes automatically maintain the arc at the focus of the reflector, thus eliminating from the duties of the motorman the trouble of frequent adjustment. The positive electrode consists of a stationary copper forging sheathed in suitable metal to prevent it from oxidising. It has a life of about 2,000 to 3,000 hours, and may be considered as "non-consuming." The negative electrode is a steel tube containing a mixture of iron oxide and other substances. It has a life of from 60 to 80 hours.

"Some New Types of Dynamometers."—In a Paper with this title, which was read at the meeting of the Institution of Mechanical Engineers at Zurich by Dr. A. Amsler, the author described two types of dynamometers, one of which is suitable for high speed and the other for low-speed machines. The former of these is of the torsion type, and consists of three discs, one at one end of the shaft whose torque is required, and the other two at the other end. The first disc is provided with a transparent circumferential celluloid scale, which can be observed from the third disc through a fine slit in the second. This fine slit acts, in fact, as a pointer, and the amount of torsion can thus easily be read off when the scale is illuminated by a 50 c.p. lamp. Provided the shaft be perfectly elastic, the angle through which the extreme ends are turned will be proportional to the twisting moment—that is, proportional to the power transmitted. If the shaft is made of a special spring steel of very high yield point—that is, above 6,000 kg. per square centimetre (90,000 lb. per square inch)—it can be twisted to a considerable degree without breakage or permanent distortion. In the example given the twist of the rod 40 cm. (15¾ in.) long is for a twisting moment of 20 m.-kg. (1,736 in.-lb.) about 20 deg. The shaft has a cross-section of 12 mm. by 12 mm. (0·4725 in. by 0·4725 in.), and is, therefore, subjected to a stress of 5,200 kg. per square centimetre (78,000 lb. per square inch), which is below the yield point. In the second type of instrument a pulley is provided with two projections, which when in rotation press a small piston into a cylinder filled with oil. This causes a registration proportional to the torque to be given on a gauge through a mechanism similar to that of an ordinary steam indicator. A strip of paper passes under the pencil of a registering gear at a velocity proportional to the speed of the shaft of the instrument. The area of any portion of the diagram thus obtained represents the energy absorbed by the machine and the mean height the average power transmitted.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. J. H. Dellinger contributes an article on "The Expression of Resistivity of Electrical Conductors."

Mr. J. Härdén contributes an article on "The Effect of Power Factor and Load Factor in Electric Furnace Work."

We give an abstract of a Paper by Mr. L. Zodel on "High Pressure Water-Power Works," read at the recent meeting of the Institution of Mechanical Engineers at Zurich.

At this meeting Messrs. T. Weber and S. Abt contributed a Paper on "Rack-Railway Locomotives of the Swiss Mountain Railways."

At the meeting of the International Photometric Commission at Zurich last month Messrs. W. J. A. Butterfield, J. S. Haldane, F.R.S., and A. P. Trotter read a Paper on "Corrections for the Effects of Atmospheric Conditions on Photometric Flame Standards."

The Edison-Beach storage battery car was described by Mr. R. H. Beach in a Paper read before the Street Railway Association of the State of New York.

A new type of single platform prepayment tramcar is being introduced in Buffalo. This is discussed in our Leading Article.

We describe the large turbine-driven power station which supplies electric light and power in Marseilles.

Bispham Council are borrowing £10,800 for their electricity supply project.

Burnley Council have secured sanction to borrow £8,552 for extensions of generating plant.

Hornsey (London) Council have received sanction for a loan of £9,000 for extensions to the electricity undertaking.

Municipal Loans.—Dublin Corporation have received sanction to a loan of £100,000 for their electricity supply department, loans or similar purposes have been granted to Burnley Corporation (£8,552), Wrexham Corporation (about £3,600), Aldershot Council (£2,500) and Bispham Council (£10,800). Sheffield Corporation have applied for permission to borrow £61,000, Hereford for £2,350 and Briton Ferry for £1,200 for electricity supply extensions.

Companies' Meetings and Reports.—The reports of the meeting of the Central London Railway Co. and the Tyneside Tramways and Tramroads Co and the directors' reports of the Yorkshire Electric Power Co., the Liverpool Overhead Railway Co. and the Hankow Light and Power Co. are given on another page.

OBITUARY.

E. Mercadier.—The death took place on the 27th ult. of M. Ernest Mercadier, formerly director of studies at the Ecole Polytechnique, Paris. M. Mercadier entered the French telegraph service in 1859, and held the post of Director of Telegraphs during the siege of Paris, when he also organised the military telegraph service. After the war he became professor of Physics at the Ecole Supérieure de Télégraphie, and in 1881 he became director of studies at the Ecole Polytechnique, where he remained until 1903. The deceased wrote on electric telegraphy, and was the inventor of a number of technical appliances. M. Mercadier was a foreign member of the Institution of Electrical Engineers and a member of the Société Internationale des Electriciens.

W. I. Last.—We regret to record the death of Mr. William Isaac Last, science director of the Victoria and Albert Museum, South Kensington. Mr. Last was born at Dorchester in 1857, and, serving his time as a mechanical engineer, became senior Whitworth scholar in 1878. He was then engaged in engineering work both in England and South Africa till 1890, when he was appointed keeper of the machinery and inventions section at the South Kensington Museum. He was appointed senior keeper in 1900 and director in 1904.

John A. Surtees.—The death took place on Aug. 1 at the age of 33 years of Mr. John A. Surtees, who had just been appointed manager of the Cromer Electricity Works. He had been assistant engineer with the Urban Electricity Supply Co. at Grantham for eight years.

Charles William Pearson.—We also regret to record the death of Mr. C. W. Pearson, a member of Pearson Bros., electrical engineers of Nottingham. Deceased, who had been suffering from a breakdown due to overwork, was 46 years of age.

PERSONAL NOTE.

The French Government has conferred upon Mr. H. V. Browne the distinction of Officier de l'Instruction Publique, in recognition of his long and friendly relations with and services to the French colony at Barcelona, and as President of the British Chamber of Commerce for Spain and founder of the Chamber. We recently announced Mr. Browne's departure for Marseilles, where he becomes manager of the station of the Direct Spanish Telegraph Co. in that city.

APPOINTMENTS VACANT AND FILLED.

The Governing Body of the Northampton Polytechnic Institute, St. John-street, London, E.C., invite applications for the following appointments:—

1. Junior drawing office assistant in the mechanical engineering department (commencing salary £100 per annum).

2. Assistant junior demonstrator in the electrical engineering and applied physics department (commencing salary £80 per annum).

Particulars of conditions of appointment, &c., with forms of application, can be obtained from the principal, Dr. R. Mullineux Walmsley, to whom applications must be sent by 10 a.m. of Sept. 1. See an advertisement.

Digitized by Google

Applications are invited for the post of assistant to the wireless telegraph expert on H.M.S. "Vernon," Portsmouth. The appointment will be for three years. Salary £300 per annum. Applications to the Secretary of the Admiralty, Whitehall, London, S.W. See also an advertisement.

The Committee of East Ham Technical College invite applications for the post of instructor of the evening classes in telegraphy and telephony. Salary 10s. 6d. per evening. Applications to Mr. W. H. Barker, B.Sc., Technical College, East Ham. See advertisement.

Instructors in general mechanical engineering and motor car engineering are required for Guildford Technical Institute. Fee not less than 10s. per evening, plus fares. Applications to Mr. F. S. Tosswill, Technical Institute, Guildford, by Aug. 16.

The Crown Agents for the Colonies give notice that they require from time to time (for service in East and West Africa) mechanics (£300) and assistant mechanics (£250) in the Telegraph Department, civil and mechanical engineers (£300 to £400) and draughtsmen (£250 to £300) in the Public Works Department. Application forms from the Crown Agents for the Colonies, Whitehall Gardens, London, S.W.

A draughtsman, used to a.c. and d.c. machines, is wanted by the Lancashire Dynamo & Motor Co. (Ltd.), Trafford Park, Manchester.

The Borough of Aston Manor Education Committee require an assistant master qualified to teach electrical and mechanical engineering and mathematics (especially practical). Commencing salary £160. Applications to Mr. H. Norwood, Education Offices, Aston Manor, near Birmingham, by Aug. 28.

A demonstrator or assistant lecturer is required in the Physical Laboratory of University College, Reading. Commencing salary £125. Particulars from the Registrar. Applications by Aug. 28.

The Council of the University College of Nottingham have appointed Mr. W. H. McMillan, B.Sc., of Glasgow University, to be the first occupant of the newly-founded Chair of Mining at the college.

Mr. I. Bulfin, electrical engineer at Bournemouth, has been also appointed general manager of the Corporation tramways in succession to Mr. C. W. Hill.

Mr. A. G. Balfour (Dartford) has been appointed general manager of the Carlisle Tramways.

Mr. S. T. Biddell, shift engineer at Watford, having resigned, Mr. L. B. Dent has been appointed to the vacancy, and Mr. F. Craven, improver, has been appointed junior shift engineer.

Sir Alexander King, K.C.B., has been appointed secretary to the Post Office, in place of Sir Matthew Nathan, G.C.M.G., now chairman of the Board of Inland Revenue.

Mr. Ayton has been appointed by Winchester Corporation city electrical engineer and manager of the electricity undertaking.

INSTITUTIONS AND SOCIETIES.

Institute of Metals.—The annual autumn meeting of the Institute of Metals will be held at Newcastle-on-Tyne on September 20th, 21st and 22nd. The Hon. Sir Chas. A. Parsons, K.C.B., F.R.S., is acting as chairman of the local committee, and Dr. J. T. Dunn as honorary secretary. The meeting will open at 10 a.m. on Wednesday, September 20th, when the members will be welcomed at Armstrong College by the Rt. Hon. the Lord Mayor of Newcastle, Sir W. H. Stephenson, and the local committee, after which a series of Papers will be read and discussed, Sir Gerard A. Muntz, Bart., president, being in the chair. In the afternoon members will have the opportunity of visiting shipbuilding, engineering, metallurgical and electrical works in the neighbourhood. In the evening there will be a reception of the members and their ladies, followed by a conversazione in the Laing Art Gallery, by invitation of the Rt. Hon. the Lord Mayor. On Thursday, September 21st, Papers will be read and discussed at a morning session of the Institute, and in the afternoon there will be further visits to works. For September 22nd the Tyne Improvement Commissioners have kindly placed a steamer at the disposal of the local committee for a voyage to the mouth of the river Tyne and back.

EDUCATIONAL NOTICES.

University of London, University College.—The next session begins on Monday, Oct. 2, and students desirous of entering the faculty of engineering with a view to taking a degree or diploma course must have passed matriculation or some other examination accepted in lieu thereof. The fee for the full three year diploma course, including the course for graduation (B.Sc.) in the faculty of engineering, is 120 guineas, payable in three instalments. There are special courses for students who have already undergone a partial training elsewhere, and these may obtain a general certificate in engineering after not less than two consecutive sessions. Graduates in science or engineering, or students who have done work equivalent to a degree, may be admitted to special courses of study to prosecute original research. An interim scholarship of the value of 120 guineas will be competed for in September. Intending students should communicate with the Provost as soon as possible, and in any case not later than Sept. 16. Further particulars may be obtained from the secretary, Mr. Walter W. Seton, M.A., Gower-street, W.C.

University of Sheffield.—The faculty of applied science comprises the departments of engineering, metallurgy, coal mining and architecture. The courses in engineering or in metallurgy extend over three years and prepare respectively for the degree of B.Eng. or B.Met. of the university. The lecture courses commence on Oct. 4 and the technical laboratory courses on Sept. 18. Prospectuses and other particulars from the registrar, Mr. W. M. Gibbons.

University of Durham.—Armstrong College, Newcastle-upon-Tyne—The 1911-12 session commences Sept. 25. There are departments of mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars may be obtained from the secretary, Mr. F. H. Pruen, M.A.

University of Birmingham.—The session commences Oct. 2. The full courses extend over four years, and students who enter after matriculations and who pass successfully the examinations at the end of each year will be entitled to the degree of Bachelor of Science in the branch of engineering to which they devote themselves. The technical engineering classes are detailed, and a list of the professors lecturers, &c., is given in an announcement on another page.

City and Guilds Technical College.—This college provides a scientific training for students preparing to become electrical and mechanical engineers or chemists, and for engineering pupils who desire to supplement their practical training by a two years' course of instruction in the principles of engineering science. There are also arrangements for three-year courses in engineering. Particulars at the college, Leonard-street, City-road, London, E.C., or from the City and Guilds of London Institute, Gresham College, Basinghall street, London, E.C.

Northampton Polytechnic Institute, Clerkenwell, London.—Full day courses in the theory and practice of mechanical and electrical engineering, and in electro-chemistry will commence on Oct. 2. The entrance examinations will take place on Sept. 27 and 28, at which five entrance scholarships will be offered. The courses for mechanical and electrical engineering include periods spent in commercial works shops, and extend over four years, and they also prepare for the degree of B.Sc. in engineering at the University of London. There are also full and partial day courses in technical optics. Particulars from the Principal, Dr. R. Mullineux Walmsley.

Glasgow and West of Scotland Technical College.—The diploma of the college is granted in the departments of civil, electrical and mechanical engineering, mining, naval architecture, chemistry, metallurgy, mathematics and physics, building and textile manufactures. The courses of study usually extend over three sessions and holders of the diploma are eligible for the degree of B.Sc. in engineering of the University of Glasgow, after attendance for at least one session at prescribed university classes. The laboratories are well equipped, and facilities for research are afforded in the departments of physics, electrical engineering, chemistry, metallurgy, mechanics, &c. The preliminary examination begins on Sept. 25, and names of candidates must be sent in by Sept. 1. The day classes begin Sept. 26 and the evening classes Sept. 21. Calendar (by post 1s. 4d.) and prospectuses (gratis) will be sent on application to the Director.

City of Bradford Technical College.—At this college there are day courses qualifying for the college diploma in civil, mechanical and electrical engineering. The next session commences Sept. 25. The new power house, especially arranged for experimental and educational work, will be opened during the session, and the equipment of the electrical engineering laboratories and machine shops has also been considerably extended and brought up to date. Calendar, containing particulars of all courses, on application to the director of education, Mr. A. C. Coffin.

ARRANGEMENTS FOR THE WEEK.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued:—

Head-quarters will be closed for instruction, but will be open for work as under until further orders:—

Monday to Friday, 10 a.m. to 4 p.m.

Saturday, 10 a.m. to 12 noon.

Digitized by Google

MANCHESTER CORPORATION TRAMWAYS.

In their electric tramway undertaking the Manchester Corporation possess a most valuable asset, and one which must prove very popular with the ratepayers, since the annual contribution in relief of the rates has shown a tendency to increase from year to year. The amount paid over for this purpose for the year ended March 31, 1911, was £75,000, bringing the total contributions during the last 10 years to £527,000.

During the 12 months in question the aggregate length of single track open for traffic has been increased by 1 mile, bringing the total (including the lines over which the Corporation are exercising running powers) to 183 miles, whilst 18 new cars were put in service. The number of cars in stock on March 31st last was 600, 321 of these being of the single truck type, 234 double truck and 45 combination.

A very satisfactory feature of the year's report is that the number of passengers carried shows a greater increase than for several years past; the total of 165,800,077 represents 184 journeys per annum per head of population served (approximately 900,000). The number of car-miles was 17,367,200, as against 17,161,774 a year ago, the number of passengers per car-mile having risen from 9·26 to 9·55. The total number of units used was 29,063,006, or 1·673 per car-mile, compared with 1·709 in the previous year.

As regards the financial results, the average traffic revenue per car-mile was 11·043d., as against 10·869d. last year, the respective totals being £799,079 and £777,219. The working expenses were 64·08 per cent. of the receipts, and amounted to 7·174d. per car-mile. The average fare paid per passenger was 1·16d., as against 1·17d. a year ago, and the percentage of passengers carried at the various fares also shows little change. Halfpenny fare passengers only amount to 8·29 per cent. of the total number, as against 8·40 per cent. last year. It should be noted in this connection that ½d. fares have only been adopted on the circular and cross routes, and not on the main routes. Passengers paying 1d. fares are 67·11 per cent. of the total, whilst 1½d. and 2d. fares account for 14·75 and 6·05 per cent. respectively.

The parcels department of the tramways continues to make progress, as will be seen by the following figures :—

	1911.	1910.
Number of parcels carried	948,074	835,734
Total receipts	£10,018	£8,678
Total profits	£2,484	£2,264

We give below an analysis of the various items in the tramway revenue account, together with the cost per car-mile of each item, the corresponding figures for the previous year being also given :—

		Cost per car-mile. 1911.	1910.
Traffic Expenses.			
Superintendence	£2,408	0·03d.	0·03d.
Wages of drivers and conductors	143,764	1·99d.	1·99d.
Wages of other traffic employés	23,891	0·33d.	0·32d.
Cleaning and oiling cars	24,283	0·34d.	0·34d.
Cleaning track	2,681	0·04d.	0·04d.
Depôt expenses	12,550	0·17d.	0·16d.
Ticket check	10,565	0·15d.	0·16d.
Uniforms	6,087	0·08d.	0·09d.
Miscellaneous	1,612	0·02d.	0·03d.
Total Traffic Expenses	£227,841	3·15d.	3·16d.
Repairs and Maintenance.			
Permanent way	£17,499	0·24d.	0·23d.
Electrical equipment of line	8,022	0·11d.	0·14d.
Buildings, &c.	4,109	0·06d.	0·05d.
Machinery	679	0·01d.	0·01d.
Cars	57,631	0·79d.	0·78d.
Other rolling stock	1,215	0·02d.	0·01d.
Total Repairs and Maintenance	£89,155	1·23d.	1·22d.
General Expenses.			
Salaries	£11,851	0·16d.	0·15d.
Store expenses	1,180	0·02d.	0·02d.
Rents	4,004	0·06d.	0·06d.
Rates	41,313	0·57d.	0·54d.
Printing and stationery	1,303	0·02d.	0·02d.
Compensation	8,704	0·12d.	0·14d.
Miscellaneous	12,136	0·16d.	0·11d.
Total General Expenses	£80,491	1·11d.	1·04d.
Power Expenses			
Current purchased at average price of 1·004d. per unit	£121,655	1·68d.	1·73d.
TOTAL WORKING EXPENSES (ex. capital charges)	£519,142	7·17d.	7·15d.
Capital Charges, &c.			
Interest	£55,227	0·76d.	0·75d.
Sinking fund	48,709	0·67d.	0·66d.
Income tax	7,083	0·10d.	0·08d.
Rent of leased lines	24,597	0·34d.	0·36d.
Promotion of bills and miscellaneous	1,638	0·02d.	0·02d.
Total Capital Charges, &c.	£137,254	1·89d.	1·87d.
TOTAL EXPENSES (inc. capital charges, &c.)	£656,396	9·06d.	9·02d.
Revenue			
Traffic revenue	£799,079	11·04d.	10·87d.
Miscellaneous revenue	8,531	0·12d.	0·12d.
Parcels department	2,484	0·03d.	0·03d.
Bank and other interest	11,616	0·16d.	0·08d.
TOTAL REVENUE from all sources	£821,710	11·35d.	11·10d.
Balance	£165,314	2·29d.	2·08d.

This balance is allocated as follows :—

Reserve, renewals and depreciation fund	£86,250	1·19d.	0·98d.
Street improvements	4,064	0·06d.	0·05d.
Contribution in aid of rates	75,000	1·04d.	1·05d.
	£165,314	2·29d.	2·08d.

The contribution in aid of rates is, as mentioned above, a similar amount to that provided a year ago, whilst the provision for renewals and depreciation is greater—viz., £86,250, as against £70,021. The present very satisfactory contribution brings the total amount of this fund at March 31, 1911, to £431,182. The outlay on renewals during the 12 months was as follows : Permanent way £59,590, overhead equipment £3,350, cars £8,469.

The outlay on capital expenditure during the year was £23,567, bringing the total to £1,981,161. This is distributed between the various items as follows :—

		Per cent. of total.
Permanent way	£654,872	33·0
Overhead equipment	182,784	9·2
Depôts and car sheds	386,344	19·5
Tramway shelters	1,874	0·1
Cash offices	3,940	0·2
Rolling stock	395,030	19·9
Machinery and plant	12,813	0·7
Office furniture	6,445	0·3
Cost of Carriage Co.'s undertaking	291,553	14·8
Preliminary expenses	25,751	1·3
Promotion expenses	19,755	1·0
Total outlay	£1,981,161	100·0

HIGH-PRESSURE WATER-POWER WORKS.*

BY L. ZODEL
(of Zürich).

Summary.—The author first indicates the method employed in classifying water-power plants into high, medium and low pressure, and the conditions which make the choice of any of these desirable, and when storage reservoirs should be included. A number of recent high-pressure hydro-electric stations and the more interesting points in the design of their pipe lines are then described.

It is necessary to divide water-powers into three classes, namely, low, medium and high head. Certainly there is no well-defined limit, but for general convenience we may call low-pressure plants those with a head of from 1 m. to 10 m. (32·8 ft.) or to perhaps 15 m. (49 ft.); medium-pressure those from 10 m. to 100 m. (328 ft.); and high-pressure those over 100 m. or 200 m. (656 ft.). The water-turbine builder has a much sharper and more precise distinction. He calls low-pressure plants those in which the turbines are placed in open flumes; medium-pressure those in which the turbine is placed in closed casings (such as pipes, drums, spirals, &c.); and high-pressure those in which impulse wheels are employed.

It is also possible to classify such plants according to the volume of water utilised. Thus, with the same head, a station might be

* Abstract of a Paper read at the meeting of the Institution of Mechanical Engineers at Zürich.

Digitized by Google

termed medium-pressure or high-pressure, according as the discharge utilised was large or small. A plant with, for example, 100 m. head and a very large volume of water, say 20 cub. m. (716 cub. ft.) per second, would be considered one of medium head, because a closed reaction turbine having a draught tube would be employed; yet the same head with only 1 cub. m. (35 cub. ft.) per second would certainly constitute a high-pressure plant, for impulse turbines would be installed.

High-pressure plants usually work out considerably cheaper than low-pressure for the same power, but a long transmission line may so increase the capital outlay on the former that a low-pressure station nearer the consumer is preferable. All such questions must be carefully worked out for the particular case in hand. A very great advantage possessed by high-pressure plants over low-pressure, and shared to a large extent by medium-pressure also, is the readiness with which the irregular flow of rivers may be regulated to supply a constant-power demand by means of storage reservoirs and weirs. With these it becomes possible to utilise the whole of the rainfall of a district and to store the water till required by the power consumer. Thus we may say that such storage plants are by far the more rational proposition. Storage, however, increases the cost of a station very considerably, and the amount of such storage must be limited to such capital charges as will be borne by the plant as a paying concern. The greater the head of water the more rational will a storage reservoir be, since the same quantity of accumulated water will represent a proportionately larger store of energy.

Questions of national economy, and of political or even strategic importance, are often solved by water-power stations, besides the immediate interests of the promoters of the scheme. This is especially the case in countries such as Switzerland, which have no coal or other natural fuel, and have to depend on foreign States for their supply; hydro-electric stations represent the foundation of their industrial security and independence.

Many large high-pressure stations, with both natural and artificial storage reservoirs, have been built within the last few years all over the world. Some of these are described in the Paper, reference being more particularly made to the pipe lines and conduits carrying the water from the lake or river to the turbines. For it is exactly to these pipe lines that too little attention is usually devoted. Many people, and not a few engineers, consider that the pipe line is a secondary part of a hydraulic power plant, so long as the thickness of the pipe allows a good factor of safety against the pressure, and a continuous line has been laid over the ground from the intake to the turbine. Hence it is that pipe lines are often built by engineers who are experts in the choice of material and in the manufacture of a pipe, but who do not understand the essentially important functions which a complete pipe line, and especially a high-pressure pipe line, has to fulfil. The general arrangement, the relative dimensions of different parts of the pipe line, the methods of anchoring and placing of fixed points, are all such important factors that they can only be properly determined by the turbine builder, because on them depends to a very great extent the proper working of his turbine, and hence the success of the whole plant.

As a first step towards the enlargement of their power house at Necaxa, the Mexican Light & Power Co. decided to increase the capacity of the existing six 8,200 H.P. turbines to 11,000 H.P. each, by fitting new runners and new nozzles. This was successfully carried out, and is an interesting case, since the velocity of the water in each of the six pipe lines supplying the six turbines was thereby increased to 5·5 m. (18 ft.) per second. This is an exceptionally high figure, but was not found to be injurious in any way. The capacity of the station thus became 66,000 H.P.

The next step was the erection of two new units of 16,000 H.P. each. These are supplied with water through a new pipe-line system which has been just recently erected. A new low-pressure feeder pipe starts from the intake tower in the Necaxa reservoir and joins with another feeder which is arranged to draw water directly from the conduit, connecting the Tenango and Necaxa basins. Interconnecting valves are arranged between these feeders. The new feeder is laid in cuts and tunnels parallel to the first to a receiver, from which the two new pressure pipe lines descend in a separate tunnel to the power house. The two high-pressure pipes are arranged in four sections of 1,160, 1,100, 1,075 and 1,040 mm. (46, 43, 42 and 41 in.) diameter respectively, having a total length of about 680 m. (2,230 ft.). The maximum velocity in these pipes is 4·7 m. (15·4 ft.) per second. The new pipe-line system is thus almost a completely parallel construction with that first built, and is in every way similar, though on a considerably larger scale. The capacity of the power station is now 98,000 H.P.

The pipe line at the power house of the Rio de Janeiro Tramway, Light & Power Co. on the Lages River, where a very large reservoir has also been constructed, has a great similarity to that of Necaxa, and is made in two sections, consisting of two upper low-pressure pipes and of six main high-pressure pipes for the lower portion leading to the power house.

This upper system of pipes consists of two independent riveted steel feeder pipes 2,435 mm. (8 ft.) in diameter, with a total length of 1,684 m. (5,530 ft.). These are an interesting feature, as at Necaxa, in that they replace the open flume or conduit which up to the present has been the more usual construction, but would have caused considerable difficulty here. The steel feeder pipes have the great advantage that, being under pressure, they utilise the full head obtained at all times in the reservoir. They are built of plate varying in thickness from 6·4 mm. to 16 mm. ($\frac{1}{4}$ in. to $\frac{5}{8}$ in.), and are under a maximum pressure head of 56·78 m. (186 ft.). The average fall of the pipes varies from 0·15 per cent. to 9 per cent.; they pass through three tunnels with lengths of 187, 88 and 436 m., and a valley is crossed by means of an inverted siphon 131 m. long and 29 m. deep. At about half-way between the intake and the receiver, at the exit of the third tunnel, each pipe is provided with an 8 ft. stand pipe, 16 m. (52 ft.) high, open to the atmosphere, carried above the spillway level, for the purpose of equalising any pressure oscillations due to water hammer. The two feeders each connect to a receiver pipe under a pressure head of 57 m. at an elevation of 347 m., and a second pair of stand pipes 8 ft. in diameter are taken up the side of the hill to the same height as the other two, in order to equalise pressure oscillations at this point. A valve house is provided, enclosing the two receiver pipes and containing a 2,435 mm. (8 ft.) sluice valve on each feeder, a 1,525 mm. (5 ft.) valve between the two feeders, and 915 mm. (3 ft.) valves at the top of each pressure pipe leading from the receivers to the power house. The latter valves can be closed by little Pelton-wheel turbines, supplied with water from the receiver and started by solenoids actuated from the power house, so that water can be quickly shut off from the 915 mm. (3 ft.) pipes in cases of emergency.

Three lines of high-pressure 915 mm. (3 ft.) pipes start from each receiver, and each of the six lines connects to a 9,000 H.P. turbine. A seventh pipe line of 305 mm. (1 ft.) diameter passes from both receivers to drive the exciter turbine sets. The main high-pressure pipe lines have a thickness of from 10 mm. to 26 mm. (0·4 in. to 1·02 in.), and are 670 m. long; the pipes are lap-welded steel of 10 m. length with flanged ends, held together by loose rings. A 150 mm. (6 in.) stand pipe, carried above the spillway level, is provided on each high-pressure pipe line just behind the sluice valves next the receiver, so that the whole arrangement with the pressure receivers approaches the conditions of an open penstock chamber and has been eminently satisfactory. The whole pressure system is divided into two completely separate and self-contained units, and this provides great safety in operation. The velocity of flow in the pipes is 4·4 m. per second. The power house is constructed entirely of steel and concrete, 72 m. long, 29 m. wide and 24 m. high. 2,500 tons of steel were used.

The six turbines are impulse-wheel machines, built by Escher Wyss & Co., with vertical shaft and four needle nozzles symmetrically arranged round the cast-steel wheel disc, which has an effective diameter of 2,120 mm. (84 in.), and is provided with 18 cast-steel buckets. They are designed for a head of 273 m. to 290 m., and generate 9,000 H.P. at 300 revs. per min. An oil-pressure thrust bearing supports the turbine and generator rotors, which amount to 40 tons dead weight. These bearings are supplied with pressure oil by three-throw pumps, which also feed the turbine governors. A pressure-relief valve is arranged to limit rise of pressure in the pipes to 10 per cent. on throwing full load off the turbine. Two exciter units of 400 H.P. each are provided.

The generators supply three-phase current at 6,000 volts and 50 frequency, which is stepped up through transformers to a line voltage of 88,000 for transmission to Rio de Janeiro, the distance being 88·5 km. (55 miles). Up to the present time turbines developing a total of 54,000 H.P. have been installed, and sanction has just been given for a further increase of units of 19,000 H.P. each. The author next describes the Tyssedalen station in Norway (*see* THE ELECTRICIAN, Vol. LXVII., p. 250), and the Brusio stations in Italy which contains no special features.

At the Siagne station, in the Alpes Maritimes province of south eastern France, two parallel pipes were provided, each 900 mm. (35·4 in.) diameter, built of single pipes about 6 m. long of rivete plate of from 4 mm. to 25 mm. thickness, the individual pipes being riveted together *in situ*. The pipes rested on masonry pedestals and closely followed the surface of the ground, so that the pipe line consisted of a large number of inclines and angles in every direction. About 40 m. vertically above the station they formed a kind of distributing pipe from which the connecting pipes branched off to the turbines. Above this distributing pipe, the pipe lines rose at a very steep angle, in places almost vertically, to a point 90 m. below the

Digitized by Google

intake. From this point they turned to the left and led for a considerable distance at a very slight gradient to the penstock chamber.

The principal faults in the arrangement of this line were as follows: (1) Too great a length of the upper portion, under low pressure, with pipes of small thickness, whereby a continual working or respirating phenomenon became apparent in this part of the pipe line. (2) Insufficient fixing or anchoring of the pipes in the lower portion of the line, and a most curious position of the distributing pipe, in which very harmful vibration combined with displacement of the pipes could take place on sudden variations of water velocity or shocks in the pipe line; this might easily lead to a burst, especially in the case of riveted pipes. (3) Unsuitable dimensions of the connecting pipes between distributor and the turbines, with their length too great and their diameter too small, resulting in considerable accentuation of the pressure variations.

Each pipe line formed one single rigid piece from top to bottom, and no provision was made to allow for expansion and contraction, such as the insertion of expansion joints. Expansion due to temperature changes in an exposed pipe line is, however, unavoidable, and if no arrangements are made to allow of longitudinal motion, then additional stresses will be set up in the pipe walls that will be difficult to foresee, and will cause resultant stresses which may under certain conditions have a fatal effect. It must be mentioned here that French engineers in general build pipe lines on this principle—that is, without expansion joints—and that a large number of such high-pressure pipe lines are now in continuous operation in France. This design must, nevertheless, be characterised as irrational, especially in view of the demands made, at the present day, on the pipe line of a central station with continually and rapidly changing water velocities.

Shortly after starting up the works a burst occurred about the middle of one of the pipe lines, probably owing to some such sudden variation in the pipe velocity. A longitudinal riveted joint was torn open for a length of 2 m., and the water suddenly streamed with such velocity from the gap that a large part of the upper section of the pipe was completely flattened by the vacuum which was produced in spite of large air pipes at the penstock chamber. Exhaustive investigation led to the final decision to replace the entire existing pipe lines by others over a quite different route.

The new line has been in continuous operation since the spring of 1908. It consists of two parallel pipe lines of almost the same dimensions as the old, but differs therefrom in that it passes straight down the side of the mountain from the penstock chamber to a point about 30 m. to 40 m. above the power house, when it turns round and passes towards the latter through a tunnel.

The upper part of the pipe line was made as short and as steep as possible, and the lower arranged longer in proportion. The whole line is divided into six straight sections; the angle points between them are formed into main anchorages (fixed points) of solid concrete masonry, into which the pipe bends are rigidly bedded. An expansion joint is placed below each fixed point. The intermediate concrete pedestals supporting the pipe line are laid at a uniform distance of 7·90 m. apart.

These pipe lines were also riveted together *in situ*, the upper portion, up to 13 mm. (½ in.) thickness, being of riveted pipe, and the remainder of pipes lap-welded by the water-gas process. The total length of the pipe line is 876 m. (2,870 ft.), composed of three sizes of pipes of 950, 900, 850 mm. (37½, 35½ and 33½ in.) diameter respectively. The thickness varies between 7 mm. and 22 mm. Each pipe is fitted at the penstock chamber with an automatic hydraulic stop valve, also arranged to be operated electrically from the power house by means of a solenoid. This automatic hydraulic valve can be set to close at any desired maximum discharge of water; if for any reason the discharge exceeds the limit, the intake opening closes at once. The whole erection of the new pipe line was finished in six months. The result, as compared with the old pipe line, was as expected. The extraordinary surges and resonance effects of the pressure shocks, especially the visible movement and trembling of the pipes, completely disappeared. No disturbance or irregularity could be observed in the pipe line even with severe and sudden load variations during running.

The Siagne power station is used as one of the hydro-electric plants which feed the high-tension system supplying power to Nice and Cannes.

Conclusion.—The water-carrying system of a high-pressure hydraulic power scheme consists of two parts: the low-pressure part to cover most of the horizontal distance between the lake or river intake and the power house, and the high-pressure part to give the operating head for the station. The high-pressure pipe line represents one of the most costly items of the plant, and is, therefore, made as short as possible by taking the low-pressure conduit to the nearest advantageous point above the power house. There are two main types of this conduit: that in which water flows under pressure, and that with water flowing freely in an open flume. The former may be further subdivided into (1) the pressure tunnel arrangement leading to a deep penstock chamber, as in the case of the Tyssedalen and Brusio installations; and (2) the low-pressure feeder-pipe arrangement connecting to a receiver with a stand pipe, as at Necaxa and Rio de Janeiro. Both of these systems allow of the total head available at any time in the reservoir to be utilised even with large variations in water level.

The type of conduit with open flume cannot, however, utilise any head in the reservoir, and this must be lost. In the case of a long conduit, a balancing reservoir must also be constructed to provide for any sudden increase in the load, since the open flume will not draw a greater volume of water to supply a greater demand, as happens automatically with the pressure conduit. This case is illustrated in the Siagne power station. Another example is the well-known Kinloch'even plant of the British Aluminium Co. in Scotland. The choice of the arrangement of conduit most suitable for a power scheme depends entirely on the particular conditions of the works, and no rule can be laid down.

RACK-RAILWAY LOCOMOTIVES OF THE SWISS MOUNTAIN RAILWAYS.*

BY T. WEBER AND S. ABT
(of Winterthur).

Summary.—The authors describe the various railways in Switzerland which are operated either wholly or partially on a rack system. Details of both the steam and electrically worked lines are given.

The authors, after a short historical introduction and a description of the racks used on the various railways, go on to give details of the steam-operated rack railways in Switzerland. These include the Vitznau-Rigi Railway (opened in 1871, and the first rack railway used for passenger traffic in Europe), the Arth-Rigi Railway (opened in 1875) and the Pilatus Railway (opened in 1889), as well as the Generoso, Brienz-Rothorn, Glion-Rochers de Naye, Schynige Platte and Wegneralp Railways. All the above are wholly rack railways, but in 1888 the Brunig Railway, operated by locomotives adapted for both rack and adhesion working, was opened. The Visp-Zermatt, St. Gallen-Gais-Appenzell and Martigny-Chatelard Railways are also worked on this dual system.

The very great improvements made in electrical traction were naturally utilised for the working of rack railways. The Gornergrat line, which starts from the terminus of the Visp-Zermatt Railway, was the first rack railway to use electricity, and afterwards a whole series of other railways followed its example.

The Gornergrat line was opened in 1898; the gauge is 1 metre, the rack is on the Abt system; it has a length of 5·8 miles, and ascends a height of 7,740 ft. The maximum gradient is 20 per cent., and the smallest curves are 262½ ft. The locomotives are provided with two polyphase motors, each having a maximum output of 90 H.P. at 800 revs. per min., the pressure being 500 volts. The motion is conveyed to two independent rack driving wheels by means of an intermediate shaft and double spur-wheel gearing. The locomotives rest on two carrying axles having springs with a definitely controlled range. The passenger coach is suspended on the locomotive frame in accordance with Mr. Rowan's design. By this construction a part of the coach's load increases the weight of the locomotive and so prevents the rack wheels from riding. The engine is fitted with two hand brakes, each of which acts on both driving rack wheels, and an automatic brake working on the rotor axles. This brake can also be manipulated by hand, either by the engine driver or by the conductor in charge of the train. When the train is going down hill the motors act as generators.

One month after the Gornergrat Railway was opened the first part of the Jungfrau Railway was also started. The part between "Kleine Scheidegg" and "Eismeer" has a difference in level of 3,580 ft., and it was opened in 1905. The length is 3·6 miles, and the gradient is generally 25 per cent. The gauge of the line is 1 metre. Where the line is in the open cutting the curves have a radius of 328 ft., the curves in the tunnel being 656 ft. Strub's rack was first applied here and three-phase current used. The locomotive is of the same construction as the Gornergrat locomotive, its capacity being somewhat higher. The speed of the train is 4·65 miles an hour. When running down hill the braking is controlled by means of an electric resistance which is cooled by a fan. The motors then

* Abstract of a Paper read at the meeting of the Institution of Mechanical Engineers at Zürich.

Digitized by Google

work as ordinary generators owing to a special change in their connections, and the current thus generated is transformed into heat.

In the years 1900 and 1901 the Aigle–Leysin and Bex–Gryon–Villars Railways were opened as the first rack railways with continuous current. The gauge is 1 metre, the gradients are from 9 to 23 per cent., and the minimum curves 60 m. The rack is on the Abt system. The locomotives are fitted with two driving and a brake rack wheel. On these engines the Winterthur Locomotive Works pattern friction-disc coupling was first employed. It serves to reduce the shocks resulting from short-circuiting and those arising from irregularities of the rack pitch.

The Brunnen–Morschach Railway on the Vierwaldstätter See was opened in the year 1905. The line is 1¼ miles long, the mean gradient being 12·6 per cent., and the maximum gradient 17 per cent. The line rises 842 ft. and the curves are 262 ft. radius. Strub's rack gear was used in this case. The locomotives are connected to the coaches on Rowan's system. These engines have only one single driving wheel, driven by two polyphase motors, each of 80 H.P., by means of double transmitting gear. The trailing carrying axle is provided with a brake rack wheel, and it and the driving rack wheel are both braked. On both the up and down journeys a safety grip is used, in addition to which the brake wheels are fitted with guide flanges in order to provide for greater security against the wheels mounting the rails.

The Wengernalp Railway commenced to use electric driving in June, 1909, and now has 10 locomotives of 300 H.P. each. These engines are generally of the same construction as those of Gornergrat and Jungfrau. They are the only ones built for 2 ft. 7½ in. gauge, which presents great difficulties in arranging for the transmission of power and the arrangement of the brakes. The pressure on the rack wheels is equalised by means of balancing levers. This arrangement has been adopted by the Swiss Locomotive Works, as well as a system of automatic interlocking which prevents the automatic brakes from being put in action when the train is going uphill. Each locomotive is provided with two series continuous-current motors, each of 150 H.P., this full power being capable of continuous use. The motors make 750 revs. per min., and they are worked in series by bow contacts at pressures from 1,500 to 1,800 volts. Short-circuiting braking is used when running down hill.

The Stansstad–Engelberg line was opened in the year 1898, and has a length of 14 miles. It is driven by three-phase current at 750 volts. The gauge is 1 metre, and for a length of 4,920 ft. the ladder form of rack rail is used. The total ascent is 1,850 ft., and it is worked by adhesion up to 5 per cent. gradients, the steepest rack line gradient being 25 per cent. The two motors of the engine develop 150 H.P. each, and work by means of "V" gearing and an intermediate shaft to the one-rack driving wheel. A special construction of friction switch (made by the Winterthur Locomotive Works) permits the two carrying axles engaging as driving axles on the adhesion lines by means of coupling rods.

The Martigny–Chatelard Railway was opened in the year 1904. It is 11·9 miles long, is provided with a Strub rack arrangement for a length of 1½ miles, of which 1·2 miles have a gradient of 20 per cent. The adhesion part of the line has gradients up to 7 per cent., and the smallest curves have a radius of 82 ft. The locomotives on this line are worked by continuous current. Their general construction is the same as those on the Jungfrau Railway, but they are independent of the carriage. As these engines have also to work on adhesion lines with 7 per cent. gradients, they are provided with a rigid coupling by means of connecting rods between the rack driving axles and carrying axles. The locomotive is equipped with the differential Westinghouse brake. In addition to these locomotives there also are on the Martigny–Chatelard line nine motor carriages, each of which rests on two four-wheel bogies. Each bogie has two motors of 80 H.P. to 100 H.P., which, by means of spur-wheel gearing on an intermediate shaft, transmit the power to the rack as well as to the adhesion axles. This rigid connection between adhesion and rack wheels is not to be recommended, but up to date the system has worked without any interruption.

The line between Monthey and Champery was opened in 1906, and has a length of 7 miles with three heavy banks of 13 per cent. up to 13·6 per cent. It rises a total height of 398 ft. The gauge of the line is 1 metre, it is fitted with Strub rack gear, has curves of 49·7 ft. radius, and is worked by means of a mixed system of motor coaches. The portions that are worked by adhesion have maximum gradients of 5 per cent. and curves of 37·3 ft. The bogies, each of which has one adhesion and one rack-wheel driving motor, each independent of the other, allow varying gradients to be worked in the most efficient manner by the rolling stock. The adhesion axles are driven by the adhesion motor and are connected by coupling rods. The rack-wheel motor works by means of double spur gear on a rack-driving wheel mounted loose on one of the adhesion axles.

In order to make the direct communication with the steam rack railway at Glion–Rochers de Naye, which starts from the upper end of the Territet–Glion rope railway above Montreux, the Montreux–Glion line was built in the year 1909; it has a gauge of 2 ft. 7½ in., and the Abt double-flitch rack was used in order that this line might form a direct communication between Montreux and Rochers de Naye. The line has a total length of 1¾ miles, and rises 984 ft., the maximum gradient being 13 per cent. The radii of the curves are 262 ft. in the open part of the line, 197 ft. in the railway station and 164 ft. at the points.

The locomotives are arranged so that they can run either by adhesion or by the rack gear only. The two-rack driving axles are each connected to the neighbouring adhesion axles and carry a loose rack-brake wheel. The rack wheels are always in motion as they are coupled up through double spur wheel gearing to the motors. The arrangement for running on the adhesion part of the line is as follows: A friction-clutch coupling is keyed on to the intermediate shaft and transmits the power from this by spur-wheel gearing and connecting rods to the adhesion axles. In principle the general construction is that of the Engelberg locomotive.

In conclusion, it may be mentioned that the Blonay-les-Pleiades and the Altstätten–Gais Railway lines are intended to be put in service during the present summer. Both these lines have metre gauge and Strub's rack gear. The first line works with mixed locomotives similar to those on the Montreux–Glion line, the second line has six-wheeled motor carriages having bogies similar to the Monthey–Champery type.

THE EDISON-BEACH STORAGE BATTERY CAR.*

BY R. H. BEACH.

Summary.—The author describes a number of tests which have been made on cars fitted with an improved type of Edison iron-nickel accumulators. Operating costs are among the details given.

Experience with batteries composed of lead compounds immersed in acid electrolyte has been such as to lead many to think that all secondary batteries are delicate and have a short life, and therefore are to be avoided for use on vehicles. The Edison secondary battery, which is the source of energy in the Edison-Beach storage battery car, is neither delicate nor short lived. From experience extending over several years it is known that the battery will not fall off in capacity during the first six years of its life. It is guaranteed for three years, and it is believed that it will last for a much longer time especially if distilled water be used.

With the older types of storage batteries it has been necessary to allow almost as long for charging the battery as for discharging it under service conditions. The older types of batteries require about 11 hours for a complete charge, and in car operation this would mean that the car would be out of service at least half the time. Because of the fact that the Edison battery is not injured by high rates of charging, a car equipped with this type of battery need be out of service practically none of the time. In Washington, D.C., a car is operated over a line 4 miles long. The running time is 16 minutes and the layover time at the terminus is three minutes. The battery is charged at five times its normal rate during the three-minute layover, and the car then runs to the other terminal, where the operation of charging is repeated. The battery is not charged at any other time, and the car runs 204 miles each day. The three-minute layover at each terminal is required for changing the fender and giving the conductor an opportunity to re-set the fare register. Advantage is merely taken of this time to charge the battery. Another car operated in Concord, N.C., runs 99 miles a day, and is charged five times for 10 minutes at each terminal. The total charging time during the day is 3 hours and 20 minutes.

In designing the cars on which these batteries are used the writer has aimed to reduce the dead weight and to eliminate, as far as possible, friction losses. The average Pullman car weighs 3,000 lb. per seated passenger. The ordinary wooden day coach used by steam railroads weighs about 1,500 lb. per seated passenger. A steel suburban coach weighs 1,100 lb. per seated passenger. An ordinary single-truck trolley car weighs about 800 lb. per seated passenger and an ordinary double-truck car about 1,000 lb. per seated passenger. The average current consumption of a trolley car is approximately 125 watt-hours per ton-mile. The Edison-Beach double-truck storage battery car weighs only 600 lb. per seated passenger while the small single-truck car weighs 380 lb. per passenger. The latest type of long wheel base single-truck car weighs 360 lb. p

* Abstract of a Paper read at the annual meeting of the Street Railway Association of the State of New York. From the "Electric Railway Journal."

Digitized by Google

seated passenger. The weight of the battery required on each of these cars is about 60 lb. per seat.

This reduction in weight has been accomplished by making a number of departures from the usual practice in body and truck construction. All of the joints in the truck frame are welded instead of being riveted or bolted. No difficulty has been experienced from broken welds. In longitudinal seat cars an electrically welded latticed steel girder forms a rest for the seat, and extends the length of the car body. It is bolted to the side, cross sills and side posts. In an 18 ft. car these girders weigh about 300 lb., and they so stiffen the body that a reduction of nearly 3,000 lb. can be made in the weight of the other parts. A very light roof is used, because it is not necessary to support a trolley base. The body of an 18 ft. car with 5 ft. platforms and folding doors, but no bulkheads or interior doors, weighs about 3,700 lb. A standard monitor-deck car body of the same length weighs about 6,700 lb., and the light bodies with the steel girders are much stronger than the heavy bodies.

After extensive experiments had been made it was found that there was a considerable saving in friction losses if the wheels were permitted to rotate on the axles instead of having the axles fixed in the wheels and rotating in the journal bearings. Exactly how much saving in current consumption has been effected by this change is not known. A silent chain drive is used between the motors and the wheels. There is some gain in efficiency with this type of drive over the gear drive, but it is difficult to say exactly the amount. When new the gear drive is probably very nearly as efficient as the chain, but as it wears it loses its efficiency, whereas the chain does not. The chain drive possesses a great advantage over the gear drive while the car is coasting. On a test run between Athena and North Newark on the Erie Railroad, a distance of about 7 miles, a chain-driven car accelerated from 0 to 35 miles per hour, and maintained that speed on a practically constant gradient of from ½ to 1 per cent. without the use of any current. An ordinary journal-bearing car will scarcely move down this slope without the application of power. The average current consumption of the Edison-Beach storage battery car is very low, in no case exceeding 60 watt-hours per ton-mile. In a test made at Atlantic City at the time of the American Electric Railway Association Convention in October, 1910, one of these cars made 36 trips, aggregating 14·4 miles, with an average of six stops per mile and an average speed of 9 miles per hour. The average number of passengers carried was 18, and the average consumption of current per ton-mile was 54·2 watt-hours.

A double-truck car which was tested on the Greenwood Lake Division of the Erie Railroad between Forest Hill and Sterling Forest ran a total distance of 70·2 miles. The weight of the car, including passengers, was 16·53 tons, and the maximum speed was 25 miles per hour, the schedule speed being 18 miles per hour. This line has a number of heavy gradients, but the current consumption per ton-mile averaged only 49·63 watt-hours. Another test made on the Erie Railroad between West Orange and Forest Hill at the same rate of speed showed a current consumption of 46·1 watt-hours per ton-mile.

The Washington, Spa Springs & Gretta Railroad has had an Edison-Beach car in service for a number of months on a line which has gradients as steep as 8 per cent. The battery car has averaged about 355 watt-hours per car-mile, and it has been found that one of these cars consumes only about one-fourth the current required by an ordinary trolley car.

It is of interest to note the long-distance runs which may be made by these cars on a single charge of the battery. The double-truck car previously mentioned has been run on a single charge from West Orange, N.J., via Jersey City, to Middletown, N.Y., over the Erie Railroad, as the second section of an express train. The same car has run on a single charge from Jersey City to Atlantic City, N.J., over the main line of the New Jersey and the Reading Railroad, a total distance of 135 miles. Sufficient energy was left in the battery upon arrival at Atlantic City to run about 40 miles more. This car can attain a speed of 25 miles per hour on a level with full load and a speed of 16 miles per hour on a 6 per cent. gradient. It is equipped with four motors rated at 15 amps. and 200 volts and an Edison battery weighing 4,800 lb. On the single-truck cars carrying 26 passengers two motors rated at 30 amps. and 110 volts are used, and the battery weighs 1,800 lb. The lower voltage used on the single-truck cars lessens motor and controller troubles.

As showing what can be done with one of these cars on a small road, the results of operation on the Salisbury & Spencer Railway, Concord, N.C., are of interest. The total cost of this line, which is 1½ miles long, was £4,000, and the net earnings of a single car are at the rate of £1,534, which is equivalent to more than 33 per cent. on the investment. The current for charging the battery of this car is purchased from the Southern Power Co. at a price of 0·875d. per kilowatt-hour, measured on the alternating-current 'bus bar. The car is operated by one man, passengers entering and departing by the front door. The following is a record of 30 days' operation :—

Total car-miles	2,687·5
Total kilowatts	5,268·0
Kilowatts per mile	1·95
Total receipts	£197·33
Operating expenses :—	
Power at £0·35 per kilowatt	£18·44
Conductors and motormen	£46·59
Miscellaneous	22·39
Total expenses	£69·50
Net profit	£127·83

THE BUFFALO NEAR-SIDE SINGLE-PLATFORM CAR.*

Some time during next month the International Railway, Buffalo, N.Y., is to place in service 35 single-platform prepayment cars, to be known as "near-side" cars. To prepare the public for this radical change in car design and operation, the railway authorities have issued an elaborately illustrated bulletin from which the following information is taken. The first part of the bulletin sets forth the conditions which should be met by a car to give the maximum convenience and comfort to passengers and employés and to ensure the minimum liability to accidents. It is pointed out that the usual form of prepayment car, having no entrance at the front, is at a disadvantage during bad weather in such cities as Chicago, Philadelphia and Buffalo, where ordinances require the cars to be stopped at the near crossing. Furthermore, the conductor cannot see all approaching passengers from his position on the rear platform, while alighting passengers who get off at the rear and turn toward the far side of the street are in danger of being run down. Although the rear-entrance prepayment car has greatly reduced platform accidents, it still leaves the conductor's control imperfect, because he must divide his attention between collecting fares at the entrance and watching the step. The near-side prepayment car is intended not only to remove these disabilities, but also to incorporate certain other advantages, such as effective automatic ventilation and improved destination signs.

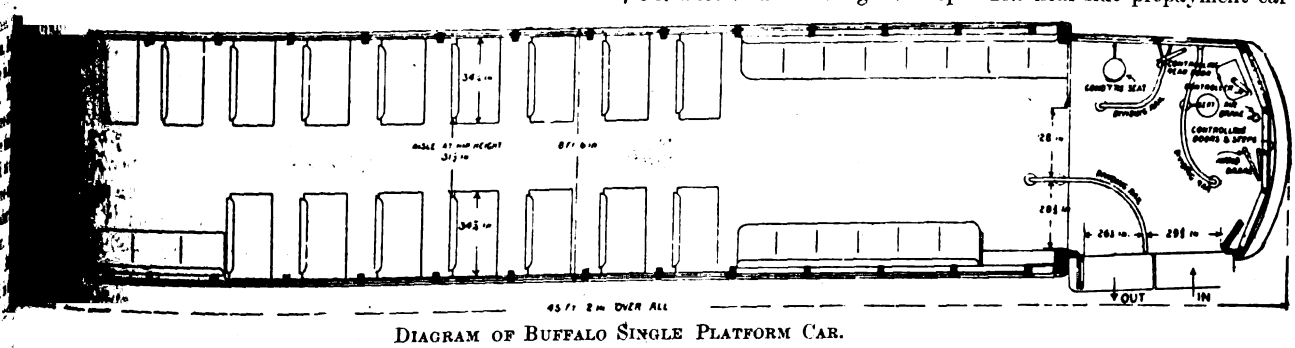

DIAGRAM OF BUFFALO SINGLE PLATFORM CAR.

As shown in the accompanying illustration, the entrance and normal exit are by way of the front platform. The plan shows a step entrance of 29¾ in. and a step exit of 26¼ in. The corresponding divisions at the front end of the car body proper are 28 in. and 28¾ in. The motorman is provided with a seat, and in the operation of his apparatus is protected from interference by a dividing rail. His vision is guarded against reflected light by installing an adjustable curtain. By means of a lever the motorman controls the entrance and exit folding doors and steps either separately or together. While the car is at a standstill the motorman can plainly see the passenger enter and leave, and is thus able to act promptly in operating the doors and steps and in getting the car under way

* From the "Electric Railway Journal." Slightly abbreviated.

Digitized by Google

without waiting for the bell signal. Passengers are not permitted to remain upon the platform when the car is in motion. This rule prevents the motorman's attention from being diverted, and consequently enables him to give all his attention to watching for passengers and avoiding collisions.

The conductor is provided with a seat within the rail space directly opposite the entrance to the front platform. In this position he is able to control the entrance passage in the body of the car. As the conductor is amply protected from the weather, he can be clothed always in the way most convenient for his work. When the car is taking on passengers the conductor collects fares and issues transfers. He is able to do this work more rapidly and accurately than heretofore because the motorman relieves him of the necessity of watching the step and of giving the starting signal. The entrance portion of the front platform will accommodate 10 to 15 oncoming passengers. When the car is in motion the conductor, whether seated or standing, directly faces the passengers, thus placing him where he can most readily observe the signals of those passengers who cannot conveniently reach the signal push-buttons. Having no other duty to perform while the car is moving, the conductor is able to call the streets as required, and as he faces the passengers the street names are much more easily heard and understood.

Passengers alighting from the car by way of the front platform and passing across in front of it have a direct view of cars or automobiles approaching from the opposite direction. Should they desire to pass behind the car from which they alight, they must necessarily await its forward movement. These conditions serve to forestall the accidents which occur when passengers alight from the rear end of the car and pass directly behind it.

It will be noted from the plan that, strictly speaking, there is no rear platform. However, a door and step are installed for emergency exit or for use at points where the car is entirely unloaded, as at parks, baseball grounds, &c. This rear exit may be operated either from the rear end of the car or by the conductor from his position on the front platform. The space heretofore required for a rear platform is utilised for a circular seat, thereby giving a largely increased seating capacity. In fact, the total seating capacity of the car is 53, as compared with 40 for a prepayment car of the same length. Of these 53 passengers 35 face forward; there is also room for 30 standing passengers, on the basis of each standing passenger occupying an oval 12 in. by 18 in.

This car, as described, operates ordinarily from one end only, necessitating loops or wyes at the ends of the line. It can, however, be run in the reverse direction in case of emergency. This single-end design permits the use of a non-reversible cross seat, which, with the semi-convertible window construction, gives a considerable increase in the width of the aisle and the width of the cross seats without increasing the overall width of the car. The adoption of maximum traction centre bearing trucks allows the use of two-motor instead of four-motor equipments, greatly reducing the weight per passenger and also reducing the height of the car floor to such a degree that the lower step is carried 2 in. nearer the ground.

Another interesting feature of the construction of this car is the use of a flat-arch roof in connection with the automatic ventilating system. Fresh air is brought in over the electric heaters, which are controlled by a thermostat, and the foul air is discharged through nine registers placed in the ceiling directly over the seat. These registers are connected with ventilators placed at intervals on the roof of the car. The vacuum created by the motion of the car draws out the foul air so rapidly that the air in the car is renewed every 3½ minutes. To provide against the inadequacy of the usual destination signs, there is used to designate the route a large illuminated white letter on a black background located in the upper half of the right-hand front vestibule window. This letter is large enough to be visible by day or night for a distance of several blocks. Supplementary thereto, a side destination sign occupies the full length of the opening immediately over the entrance and exit doors. An application of European practice is found in the "Car Full" sign, which is dropped into place below the initial destination sign whenever a maximum car load of passengers has been taken on.

The seating capacity, dimensions, weights, &c., of the near-side car, as compared with the standard pay-as-you-enter cars used in Buffalo and Chicago, are as follows:—

	Near-side car.		Pay-as-you-enter car.
Seating capacity	53	.....	40
Length of cross-seat cushion	34⅜ in.	.....	34 in.
Width of aisle at hip height	31½ in.	.....	27 in.
Width of car	8 ft. 6 in.	.....	8 ft. 6 in.
Length of car overall	45 ft. 2 in.	.....	45 ft.
Height of car	12 ft.	.....	12 ft. 5 in.
Height of lower step from ground	14 in.	.....	16 in.
Weight of car fully equipped	39,000 lb.	.....	52,000 lb.
Weight per seated passenger	736 lb.	.....	1,300 lb.

The inherent accident prevention features of this car are supplemented by the use of the H.-B. lifeguard and by a safety grab handle round the front vestibule. The handle is so designed and placed that it can be easily seized by a person about to be struck by the car who might otherwise be thrown under the platform.

ELECTRICITY SUPPLY AT MARSEILLES.

Summary.—A description is given of the station at Marseilles where direct current and alternate current at two different frequencies and voltages are generated to meet the requirements of the varying needs of the district.

A good example of a modern steam-turbine generating station is to be found at Marseilles. Marseilles is a very active centre of electrical interests, and possesses what is probably the most extensive system of tramways on the Continent. The present station was erected in order to keep pace with the increasing demands for current both for lighting and power. It is owned by the Société du Gaz et de l'Electricité de Marseille, and this company are now supplying lighting in the central and the outlying quarters of the city. Current from the steam-turbine plant is supplied to the city system at 5,500 volts and a frequency of 25. This is transmitted to a large sub-station from which the central district is supplied. From this sub-station continuous current at 220 volts is delivered to a three-wire network. The station also supplies current at 5,500 volts and a frequency of 50 to the outlying districts. Low-tension mains on the alternating system are fed from small transformer posts placed at various points, the secondary voltage being 190 volts in this case. For the power supply, especially for large motors, the company is operating a special system of high-tension mains, using a pressure of 13,500 volts delivered directly from the machines at the central station, a frequency of 25 being used. The high-tension lines owned by the company have been laid out so that in case of need they can be supplied with current from the network of power lines which covers the Maritime Alps region and runs as far as the large sub-station of Allauch, in the neighbourhood of Marseilles. This power system is the most extensive in France, and is fed from a number of hydraulic plants lying in the mountain region. It can be drawn upon if required, and inversely the Marseilles station can feed into the Allauch sub-station, so as to afford a reserve supply for the latter. Such an arrangement is therefore of mutual benefit to the two sets of power supplies. The general arrangement and elevation of the station are shown in Figs. 1 and 2.

In order to satisfy the above-mentioned conditions, the Marseilles plant has been arranged to furnish three different kinds of current at various voltages and frequencies. Current is produced by three 1,000 kw. (Fig. 3) turbines at 5,500 volts three-phase and a frequency of 25 for the supply of the central sub-station of Marseilles. For the transformer posts in the outer districts of the town current is obtained from one 1,000 kw turbine. While the voltage in these districts is the same as that in the centre of the town the frequency is 50 instead of 25. For interchange purposes a frequency-converter consisting of 50-frequency and a 25-frequency alternator coupled on the same shaft is used. Either one of these machines can act as synchronous motor so as to operate the other as an alternator and thus produce current at either of these two frequencies required.

For the supply of the high-tension lines a turbine which delivers three-phase current at 13,500 volts and a frequency of 25 is installed. In the station also there is a set of transformers having a ratio of 13,500/5,500, so that the high-tension current can be fed to the 5,500-volt bars, or *vice versa*. Care has thus been taken in laying out the station to make the above three systems interchangeable, and any one of the five turbine groups can be used to supply any of the circuits of the station in spite of the different voltages and frequencies.

The boiler room for the 1,000 kw. units contains eight multitubular boilers which are designed to work normally at a pressure of 190 lb. per sq. in. Each of these boilers has 225 sq.

metres (2,430 sq. ft.) heating surface, and is combined with a superheater of 54 sq. metres (580 sq. ft.) surface, which raises the steam to 300°C. The boiler produces 3,125 kg. (6,875 lb.) of steam per hour at the normal pressure, but this output can be increased by the use of a forced draught. For this purpose a motor-driven blast fan is employed, the yield being thus raised to 3,500 kg. (7,700 lb.) per boiler unit. A 72-tube economiser is fitted to each of the boilers, so as to heat the feed water to 80°C. This battery of eight boilers is used in connection with the three turbo-alternator units which operate at a frequency of 25. For the 50-frequency machines and also for a second turbo-alternator of the same type which is to be installed four other boilers are employed. These boilers are designed to work at the same steam pressure, but have a heating surface of 265 sq. metres (2,860 sq. ft.), and are fitted with a superheater of 65 sq. metres (700 sq. ft.) surface. Each unit produces 3,600 kg. (7,920 lb.) of steam per hour, or, by the use of a forced draught provided by the same fan, the output can be raised to 4,200 kg. (9,240 lb.) per hour. With this type of boiler is used a 96-tube economiser. Owing to the proximity of the gas works, the company can employ the gas coke from this latter plant in order to heat the boilers with economical results. The gas works lies at a height of 3·75 metres (12 ft.) above the floor of the electricity works, and thus the mouth of the coal bunkers which lie on one side of the boiler-room are on a level with the outside ground, so that the coal can be dumped directly into the bunkers without any further handling by means of the cart which circulates between the gas works and the electricity station.

The second boiler-room of the station is laid out on quite a different plan from the other, and automatic stoking is employed, together with a well-designed system of conveyors for bringing in the coke supply. The eight multitubular boilers which are here installed have a rated capacity per unit of 4,000 kg. (8,800 lb.) of steam per hour. Motor-driven blast fans are used to give a forced draught in the former case, and in this way the output can be increased to 4,800 kg. (10,500 lb.) per hour. From the coal bunkers, which are mounted on the second floor of the station and above the boilers, the coke is fed down to each of the furnaces by a series of chutes in the usual way. The bunkers are supplied by coke from the gas works. This is brought in on dump carts. The present set of eight boilers is designed for the supply of the large 3,000 kw. steam turbine.

The Curtis turbine groups (Fig. 6) for the 25-frequency current are operated at the standard speed of 1,500 revs. per min., and the steam is admitted at a mean pressure of 11·5 atmospheres, this being superheated to 275°C. These turbine alternators are designed to carry an overload of 30 per cent. for two hours' continuous running and of 50 per cent. for a 15-minute run. Steam governing is effected by the use of a ball governor, which acts through a hydraulic motor upon the main gate valves of the steam piping. A second method of regulating is by means of valves operated by a small electric motor, and this makes it possible to secure slight variations of speed. The attendant at the switchboard can control the working of the electric motor, and in this way can obtain synchronism between the different machines in a convenient manner.

The lower end of the turbine shaft is mounted in a bearing which is provided with water lubrication at a pressure of 30 lb. per sq. in., the water for this purpose being supplied by motor-driven pumps. Of the three guide bearings for the vertical shaft, the lower one is also provided with water lubrication, while the remainder have an oil feed in the usual way. Motor-driven oil pumps are used for this latter purpose, and another set of electric pumps is used for supplying the water for the hydraulic motors of the governors. Should the speed of the turbine rise above the normal by more than 15 per cent. an automatic device mounted for the purpose causes the closing of the steam gate of the inlet.

chines at 5,500 volts and the second part serves for the 500-volt machines. The 5,500-volt switchboard is divided o three main portions, one of these being used for the direct rent, the second for alternating current at 25 frequency, d the third for 50 frequency. The direct current portion of

such as lighting, boiler-room motors, frequency-converter motors, oil-pumps, &c.

The second part of the 25 frequency alternating-current board is fitted with two sets of 'bus bars, and has the following panels: Four feeder panels which by the use of extra bars and

Digitized by Google

section couplers allows any one of the outgoing cables of the station to be fed, or two or three of such cables to be supplied in parallel. This can be done by any one of the panels or by all the four panels at the same time. On these panels are mounted meters for registering the amount of energy furnished or received by the station as a whole. There are next five alternator panels—*viz.*, two panels for the alternators (or synchronous motors) of the frequency-converters working at a frequency of 25. At the lower part of each panel is placed a circular contact switch for raising or lowering the resistance which is put in series with the field winding of the starting motors of these groups, so as to be able to adjust the speed of direct-current motors and obtain synchronism of the three-phase motors of the frequency-converter, without it being necessary to leave the switchboard. There are also three panels corresponding each to a 25 frequency turbine-alternator. Each of these panels carries the

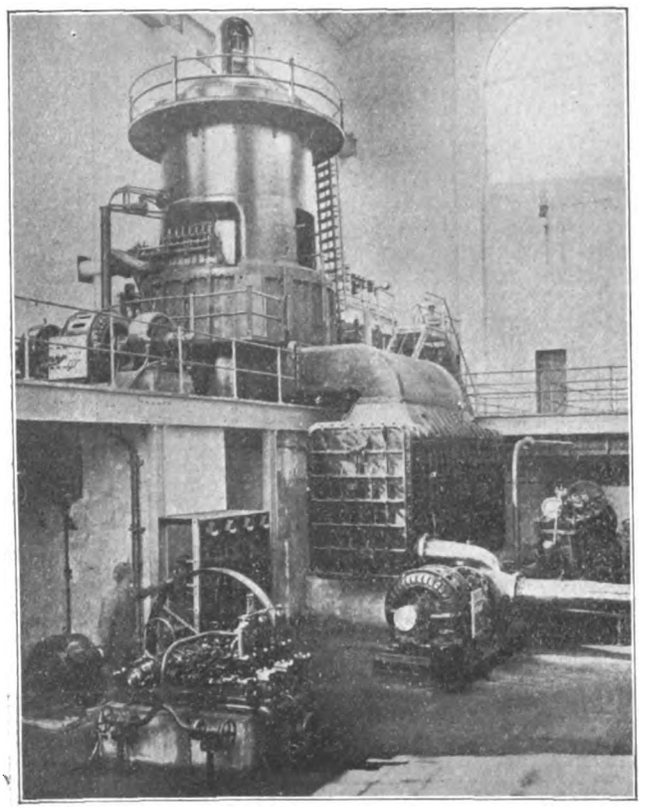

FIG. 6.—3,000 KW. CURTIS TURBINE SET WITH CONDENSER, PUMPS, AND EXCITERS.

usual switching devices for the alternator. At the base is a switch which controls the circuit of a small synchronising motor mounted at the top of each turbine. It is possible to synchronise one of the alternators with any one of the others without leaving the switchboard. There is also one panel for the high-voltage circuits of the station transformers for supplying the station circuit. This panel is provided with an automatic circuit-breaker of the oil type, and here is also one machine panel for the 13,500-volt current, and two panels for the 5,500-volt non-synchronous motors of the exciter sets.

The switchboard which is used for the current supplying the station has two sets of 'bus bars and comprises two alternator panels for the frequency-converters, three feeder panels each corresponding to an outgoing cable and one alternator panel for the fourth 1,000 kw. group. The board contains blank panels for future use and an automatic voltage regulator, which acts upon the exciter circuit of the alternators. The 13,500 kw. switchboard is mounted on an elevated platform at one end of the main dynamo room, and is laid out for two 3,000 kw. alternators, one of which is now erected. It is fitted with two machine panels and six feeder panels for 13,500 volts and 25 cycles, as well as blank panels ultimately giving four alternator and seven feeder panels. The oil switches which are operated from this switchboard are of the Thomson-Houston distant-control type. On the board is engraved a simplified plan of the circuits of the station with a number of pilot lamps, which indicate the opening or closing of the main switches, and these aid the attendant in carrying out the various operations. A view of the 13,500-volt board is shown in Fig. 4 and of the oil switches in Fig. 5.

ALTERNATE-CURRENT RESISTANCE AND INDUCTANCE OF COILS.*

BY A. ESAU.

1. *Single-layer Coils.*—When a straight cylindrical wire is traversed by a direct current, the stream-lines distribute themselves uniformly over the whole section of the wire. When the current is alternating, however, the stream-lines crowd towards the outer surface of the wire, a phenomenon known as the "skin effect." This increases the resistance and reduces the inductance. An accurate knowledge of the effect of the frequency is necessary wherever rapid oscillations are used, since the natural rate of oscillation and the damping depend upon it. Rayleigh † calculated the effect for a straight wire. Of practically greater importance are solenoids and coils, and in these the skin effect produces a concentration towards the interior of the coil, thus increasing the resistance still further. The effect has been investigated by Dolezalek, M. Wien, Sommerfeld, Batelli, Magri, Black, Cohen, Coffin, Nicholson, Lindemann and Meissner.‡

If the resistance for a certain inductance is to be a minimum, the most favourable arrangement is a coil with a single layer of wire.

Theoretical Formulæ.—Wien's general formula is

$$\frac{W}{W_0} = 1 + \frac{C}{A} n^2 \pm \ldots,$$

where W is the alternate current resistance, W_0 is the direct-current resistance, n is $2\pi \times$ frequency, and C and A are complicated

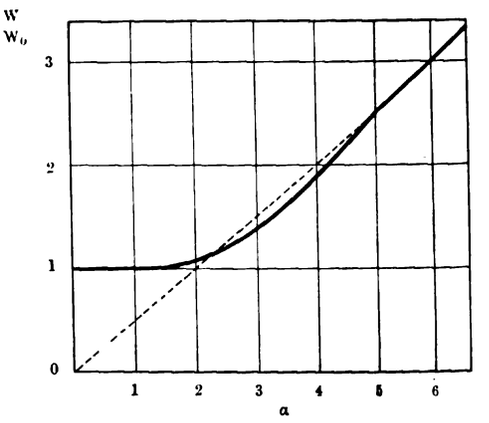

FIG. 1.

expressions involving the shape of the sectional area of the wi If the latter is an ellipse with a major axis $2b$ in the axial direct of the solenoid and 2ρ in the radial direction, the ratio becomes

$$\frac{W}{W_0} = 1 + \left[\frac{2\pi^2\rho^3\left(\frac{b}{\rho}\right)m\sigma n}{c}\right]^2 \times 0{\cdot}272,$$

where c is the length of the solenoid, m the number of turns and σ conductivity. This formula shows that if the wire is made a flatter band of elliptical section the alternate-current resistance is increas For a circular section the formula reduces to

$$\frac{W}{W_0} = 1 + \left[\frac{2\pi^2\rho^3 m\sigma n}{c}\right]^2 \times 0{\cdot}272.$$

If the section of the wire is rectangular, with the sides $2b$ (a and 2ρ (radial), the formula becomes for thin wires

$$\frac{W}{W_0} = 1 + \left(\frac{8b\rho^2\pi\sigma n}{g}\right)^2 \times 0{\cdot}356,$$

where $g = c/m$ = the pitch of the solenoid.

* Abstract of an article in the "Annalen der Physik," 34, pp. 5 and pp. 547-564, 1911.

Digitized by Google

If the wires are infinitely close together, $g=2b$, and

$$\frac{W}{W_0}=1+(4\rho^2\pi\sigma n)^2\times 0{\cdot}356.$$

Sommerfeld's formula for high frequencies is $W/W_0=a/2$, where $a=4\rho\sqrt{2\pi n\sigma}$.

The complete formula, applicable to any frequency, is

$$\frac{W}{W_0}=\frac{1+\frac{a^4}{5}+\frac{a^5}{19}+\ldots.}{1+2\frac{a^4}{\underline{|6}}+2\frac{a^5}{\underline{|10}}+\ldots.}$$

From this formula the following table of theoretical values has been calculated :—

a	W/W_0	a	W/W_0
0	1·0000	3·5	1·6183
0·5	1·00035	4·0	1·8978
1·0	1·00553	4·5	2·1903
1·5	1·0278	5·0	2·4769
2·0	1·0856	5·5	2·7493
2·5	1·1987	6·0	3·0000
3·0	1·3781	...	...

These figures are plotted in the accompanying diagram (Fig. 1).

The formula only applies so long as the section of the wire is small in comparison with the diameter of the solenoid. When the solenoid becomes narrow, the ratio W/W_0 decreases.

When the solenoid itself has a rectangular section with sides $2r_1$ and $2r_2$, the value of a becomes

$$4\rho\sqrt{\frac{2b}{g}}\sqrt{2\pi n\sigma}\sqrt[4]{\frac{4r_1r_2}{(r_1+r_2)^2}}.$$

Measurements.—These were carried out by Wien's method with Wheatstone bridge and low-resistance telephone (7 ohms). The plate of the latter was tuned to resonance for the frequency, so as to increase the sharpness of the minimum.

The general results are as follows :—

The formula of Wien and that of Sommerfeld (which are identical for the present purpose) represent correctly the increase of resistance for frequencies up to 6,000 ~ per sec.

There is a small decrease of W/W_0 with decreasing solenoid radius.

For pitches above 6ρ the ratio W/W_0 increases with increasing pitch, instead of decreasing as expected. This applies both to circular and rectangular wire sections. For high frequencies the change is satisfactorily represented by a (corrected) formula due to Piccati.*

$$\frac{W}{W_0}=1{\cdot}234\rho\sqrt{\frac{2\rho}{g}}\sqrt{2\pi n\sigma}.$$

One of the actual series of measurements is quoted below :—

Square section of wire. $2\rho=0{\cdot}3$ cm., $g=0{\cdot}8$ cm., $W_0=0{\cdot}02$ ohm.

Frequency.	a	W/W_0 calc.	W/W_0 obs.	W.
510	1·27	1·02	1·02	0·0201
1,060	1·80	1·05	1·05	0·0210
2,100	2·57	1·21	1·22	2·0244
3,060	3·10	1·43	1·43	0·0286
4,120	3·60	1·67	1·67	0·0334
5,270	4·07	1·94	1·92	0·0384
5,530	4·17	2·0	2·02	0·0404

On comparing the increase of resistance with the increase calculated by Lord Rayleigh for a straight wire, it is found that the A.C. resistance of a wire may be increased $2\frac{1}{2}$ times by winding it into a single-layer coil.

Decrease of Inductance.—This amounts to something between 1·5 and 2·5 per cent. within the range of frequencies studied. It is due to the crowding of the stream-lines towards the axis of the solenoid, which reduces the core area. The decrease is least in high-pitched wires, and is less in round wires than in wires with square section, and is well-represented by Coffin's (corrected) formula

$$\frac{L_n-L_{inf}}{L_{inf}}=\frac{1}{\sqrt{\frac{2b}{g}}\sqrt{2\pi n\sigma}}\times\frac{1}{r-\rho},$$

the higher frequencies, L_n being the inductance for frequency n, the inductance for infinitely rapid alternations and r the radius the solenoid.

* "Nuovo Cimento," 11, December, 1906.

2. *Multiple-Layer Coils.*—According to Wien, the increase of resistance in a coil on substituting alternating for direct currents is given by

$$\frac{W-W_0}{W_0}=\frac{64}{3}\frac{b^2\rho^4\pi^2m^2\sigma^2}{c^2}\left(1-\frac{(r_1+r_2)^2}{c^2}\right)n^2,$$

where W is the A.C. resistance, W_0 the D.C. resistance, b the width and ρ the thickness of the wire (of rectangular cross-section) and r_1, r_2 the inner and outer radii of the coil.

For infinitely long coils with wire of square section this may be written

$$\frac{W-W_0}{W_0}=\frac{16}{3}\rho^4\pi^2m_1^2\sigma^2n^2,$$

where m_1 is the number of layers.

Sommerfeld's formula is identical with this, except that the numerical factor is $\frac{64}{9}$ instead of $\frac{16}{3}$.

The experiments undertaken were incapable of deciding between the two formulæ. Both appear to be fairly correct for small frequencies and for a large number of layers. For the higher frequencies (4,000 to 6,000) the resistances fall below the calculated values, especially when there are only a few layers (two or three).

As regards the inductance, it is found to change least when the coil is long and the number of layers is large. The changes ranged from 1 to 8 per cent.

3. *Influence of Damping upon Resistance and Inductance.*—Barton* has studied the resistance and inductance of a straight wire for damped oscillations, such as occur in condenser discharges. He found an increase in both as compared with Rayleigh's values for undamped oscillations.

The author calculates these effects for coils by Sommerfeld's method, introducing, however, the damping factor δ. He finds for square wires and slow oscillations

$$\frac{W}{W_0}=1+\frac{16}{45}s^4\pi^2n^2\sigma^2(1+\delta^2),$$

where s is the thickness of the wire.

For rapid oscillations and small damping factors

$$\frac{W}{W_0}=s\sqrt{2\pi n\sigma}\,(1-\tfrac{1}{8}\delta^2).$$

The first formula shows an increase of resistance, and the last a decrease. In either case it is very small, being $\frac{1}{2}$ per cent. for a decrement of 0·2.

Rusch has shown that this is the actual behaviour of coils with wires of circular section.

The inductance also shows an effect of damping. For rapid oscillations the calculated relation is

$$\frac{L}{L_0}=\frac{3}{2s\sqrt{2\pi n\sigma}}(0{\cdot}1+\delta-\tfrac{1}{8}\delta^2),$$

but when the damping is considerable the formula is more complicated, and the increase may be converted into a decrease. In the case of slow oscillations the increase in the inductance is positive, zero, or negative, according as to whether the expression

$$1-\frac{21}{2s^2\pi n\sigma}\delta-\frac{15}{2}\delta^2+\frac{21}{2s^2\pi n\sigma}\delta^3+9\delta^4$$

is less than, equal to, or greater than zero.

In conclusion, the author refers to the work of Lindemann on stranded wire, which shows that an equal distribution of the stream-lines is attainable, and Meissner's work on the effect of the capacity of a coil upon its resistance, which amounts to an increase. This influence of capacity is strongest in the case of coils of many layers of thin wire. For slight damping the diameter of the strand element should not exceed 0·07 mm., and a flat coil is the best. For any given diameter of wire and wave-length it is possible to calculate the number of wires giving the smallest damping for a given inductance and dimensions.

Hydro-Electric Station in the Caucasus.—According to "The Times Engineering Supplement," the Council of Ministers has sanctioned the leasing to a British group for a term of 75 years 275 acres near the River Terek and 407 acres near Lake Soktcha for the purpose of hydro-electric stations. The Government reserve the right to acquire the works there erected within 30 years or on default of the promoters to satisfy certain regulations. The promoters have agreed to pay £2,500 annually for Government inspection. It is stated that the price of power will not exceed 1d. per kilowatt-hour.

ELECTROLYTIC CORROSION IN REINFORCED CONCRETE.*

BY C. E. MAGNUSSON and G. H. SMITH.

Summary.—After confirming the results of other investigators, that an electric current produces failure of reinforced concrete, the authors discuss the various theories of this action, reaching the conclusion that the increase in volume due to chemical action is the direct cause of the failure. Methods for protecting the concrete are finally considered.

While reinforced concrete was coming into general use as a structural material much space was given in the technical press to discussions and reports on the durability of the encased iron. The results from a large number of experiments gave fairly conclusive evidence that under ordinary conditions the iron is protected, and that even if it was rusty when placed in the concrete, it will be free from the oxide after remaining in the concrete for some time. It was quite natural therefore to infer that when failures did occur, the crack in the concrete preceded the corrosion of the iron, and that the presence of the iron in no way entered as a factor in causing the failure of the concrete. The complex chemical changes taking place for a considerable time in the hardening process of cement make it difficult to secure any chemical basis on which this inference might be refuted. Besides the complexity of the chemical changes, many variables of poorly defined range enter into the making of concrete, both in quality of material and manner of construction, so it becomes very difficult to prove that any portion of a structure where failure develops was constructed in a proper manner and from good material. Under these conditions it has become quite customary to assume that a crack in the concrete is in itself evidence of poor cement, careless construction, faulty design or some other similar factor.

Outside causes like vibrations from periodic impulses have been investigated in special cases, and for the past four years or more some attention has been given to the possible effects of electric currents. In the discussion of Knudsen's Paper a marked difference of opinion was manifest and it appeared that more experimental data would be necessary to determine the true nature of the phenomena. Accordingly, a series of experiments was begun in September, 1907, in the Electrical Engineering Laboratory of the University of Washington, for the purpose of studying the electrolytic effects on iron in reinforced concrete. The work is discussed below under three heads.

The cement used was of the "Washington" brand made at Concrete, Washington. The iron was cut into 8 in. lengths from commercial stock of ¾ in. Johnson steel bar. A copper wire was soldered to one end for making electrical contact. The ratio of cement to sand was one to three for the concrete. Cylindrical blocks 9 in. high and 6 in. in diameter were formed in moulds. The iron bar was placed along the axis and extended to within 2½ in. of the lower end, thus leaving a layer of about 2½ in. of concrete between the water in the tank and the iron bar. Each block was kept in a moist condition for at least 30 days before the E.M.F. was applied. Three blocks were made at a time, two were used in the circuit and the third kept as a check.

Will the Electric Current cause Failure in Reinforced Concrete?—The experiments supported the affirmative conclusion reached by other investigators. Modifications in applied voltage, current density and kinds of aqueous solutions did not alter the general result, viz., that an electric current passing from the iron through the concrete will cause corrosion where it leaves the iron, and, if the process be continued for a sufficient length of time, the surrounding concrete will crack.

Analysis of the Processes Involved.—The following suggestions are discussed: (*a*) Temperature rise due to RC^2 losses. (*b*) Hydrostatic pressure at the anode due to the current and to changes in solution density. (*c*) Pressure caused by the generated gases. (*d*) Chemical change in the cement, due to the current directly, destroying the cohesive strength of the concrete. (*e*) During corrosion, the iron changes to an oxide or a salt; this involves an increase in volume.

(*a*) In cases where the current is comparatively large and more heat is generated than can be dissipated without a great rise in temperature, this factor may be the cause of the failure. With sufficient heat generated to cause the water to change into steam, failure of the concrete will quickly follow. Such cases, however, are rare and readily noticed, and the flow of the current stopped. The large majority of cases deal with small currents, a few hundredths of an ampere, and the rise in temperature is slight.

(*b*) While the hydrostatic pressure at the anode is sufficient to force a few drops of discoloured water up around the edges of the iron on top of the block, the porous nature of the blocks makes it improbable that any considerable stress should come from this source.

(*c*) From the porous nature of the surrounding material it seems quite impossible that any large force should come from this source. Moreover, when two blocks are connected in series the hydrogen gas will be twice the volume of the oxygen. No action, however, was observed where the hydrogen was liberated, while the block receiving the oxygen cracked in 19 hours.

(*d*) In order to determine what action, if any, was produced directly on the concrete by the electric current the resistance of cement and concrete was first measured under various conditions; special cubical blocks being made and afterwards tested for their compressive strength.

The results of the tests recorded in the Paper may be summarised as follows:—(1) Concrete and cement, when dry, are good insulators. Their specific resistances being of the order of 1,000 megohms per cubic centimetre. (2) The conductivity of concrete and cement depends upon the porosity of the material and the nature of the solution in the pores. When the pores are full with an aqueous sodium chloride solution, both cement and concrete are fairly good conductors of electricity. (3) The current flowing through the concrete probably follows the ordinary laws of electrolysis, with the liquid in the porous spaces of the concrete mass as the conductor. (4) An electric current of low density passing through cement or concrete does not affect the compressive strength of the cement or concrete.

(*e*) When the current leaves the iron through an aqueous solution, oxygen and, under some conditions, chlorine will be liberated at the iron surface. An iron oxide or a salt will be formed and these chemical changes are accompanied by an increase in volume. When iron is changed to ferric oxide (Fe_2O_3), the volume is increased in the ratio 1 to 2·2, and a similar increase occurs when the other compounds are formed. Without doubt the forces produced by chemical action are ample to break the concrete, and all the observed facts can readily be explained on this basis. The observed data give evidence that the corrosion of the iron, caused by the electric current, precedes the crack in the concrete; and that the increase in volume when the iron changes into an oxide or a salt is the direct cause of the failure of the concrete.

Methods for Protecting the Concrete.—Five methods are discussed, viz., (*a*) Keeping the iron negative to the surrounding concrete so that the current will flow to the iron in all cases. (*b*) Using alternating currents. (*c*) Filling the pores of the surrounding concrete with some non-conducting material. (*d*) Coating the iron with a metal so that the conduction will be metallic instead of electrolytic when the current reaches the iron. (*e*) Coating the iron with some insulating material before it is placed in the concrete.

As regards (*a*), this is usually impracticable. Experiments showed that unless the currents are large enough to produce excessive heating no deteriorating effect will come to the reinforced concrete from alternating currents of equal positive and negative wave forms. The conclusion is also reached that it is not likely that any combination can be found which will so fill the pores that the moisture will be excluded and the concrete become a non-conductor of electricity.

In regard to (*d*), coating the iron with zinc proved useless. Bearing in mind the eletcrolytic properties of aluminium, the bars were covered with two or three coats of aluminium paint, using banana oil (amyl acetate) as a binder. There was observed the characteristic drop in current—that is, the rapid rise in resistance due to the formation of aluminium oxide—and when the circuit was broken recovery occurred. The paint, however, did not protect the iron from corrosion. The time element, before failure of the concrete occurred, was considerably increased, but the blocks cracked as in the case of bare iron. Two explanations are suggested. First, the salt water solution, the chlorine given off at the cathode attacks the aluminium and thus destroys the protective qualities of the oxide film, and when the aluminium has all been changed to a salt, the current can attack the iron. Second, the oxygen ions pass between the layers of aluminium flakes and thus reach the iron. The latter process seems to be the most probable. With the iron coated by a continuous layer of aluminium so as to eliminate the passage-way for the oxygen ions to the iron, the desired results might be achieved. Iron bars plated with aluminium were not available but it seems likely that the automatic increase in resistance would follow in a manner similar to the experiments on aluminium wire. With a practical method of coating the iron with aluminium, the problem of protecting the reinforcing bars in concrete from electrolytic action may be solved.

If the iron bar be coated with an insulating compound before being placed in the concrete, thus preventing the flow of electricity, it is evident that there will be no corrosion of the iron. To find a material with which such an insulating coating can readily be placed on the iron so as to produce commercially practical results is no easy task

* Abstract of a Paper read at the Annual Convention of the American Institute of Electrical Engineers.

Digitized by Google

Work has been done on this problem by Dr. Maximilian Toch who has prepared a special paint for which he claims protective properties. This and a number of other commercial paints were tested and a summary of the observations is given in the Paper. The results indicate that the time element is an important factor in determining the protective qualities of a paint. The deterioration of the insulating power of the paint is probably due to a slow absorption of moisture. In one case no indication of corrosion was seen during the first four months, while complete failure followed by continuing the process two months longer. Three sets of blocks gave no evidence of corrosion; but whether the concrete will be protected indefinitely or failure will follow by continuing the process for a few more months remains to be seen.

It was found also that the presence of the paint greatly reduced the maximum shearing force.

PROTECTION FROM LIGHTNING.

A report on this subject was presented at the recent meeting at New York of the National Electric Light Association. Twenty power supply companies who had investigated the matter very thoroughly were circularised, and the report (of which an abstract was given in the "Electrical World") is based on the replies received. It states that with improvements in insulation and lightning arresters failure of apparatus from lightning is becoming very much less frequent.

The results obtained from the use of the electrolytic type of arrester have been very satisfactory. Arresters of the horn type are in common use, but in a great many cases are being rapidly replaced by those of the electrolytic type. On the other hand, an objection to the electrolytic arrester is its high first cost and the necessity of frequent charging and attention; indeed, in a station of minor importance it has been considered cheaper to replace an occasional damaged transformer. Transmission lines having overhead earth wires appear to have suffered the least damage. The use of an earthed metal ring for each insulator is reported as being effective for the elimination of line disturbances, but is no protection against a direct stroke and is expensive. In some cases an earthed spark-gap has been provided for each insulator, and still another form is that of installing an earthed wire on each pole, carrying it well above the top. A special device, known as an arc suppressor, is now being experimented with for the relief of transmission line troubles due to an arc around the insulator, the device being used at the 'bus bars of the principal station to take care of the entire system.

In its recommendations the Committee states that where all lines leading into a station are operated separately, each of them should be provided with an arrester installed on the line side of all apparatus. In other cases experience justifies installing one arrester on the common 'bus bar. The installation is recommended of choke coils on every circuit leading to the generating station, advantage also being taken of the newer and improved types of insulation for transformers and other classes of apparatus connected with a high-tension system that are especially susceptible to damage from lightning or surges. In the case of stations where no arresters are being used the electrolytic type is recommended; if, however, arresters of the multi-gap or horn type are in use and giving satisfactory service there is no need for a change. The Committee unqualifiedly recommend the use of the overhead earth wire, which should be earthed at every supporting structure, either pole or tower. A lightning rod carried down the earth wire is also recommended.

The results of investigations have shown that a lightning arrester will not protect any apparatus on a distributing system more than 300 or 500 ft. away. A calculation is given showing that it would pay to increase the number of arresters beyond one for each $1,000 worth of transformers. The Committee repeats its recommendation as to the inspection of arresters, as well as to the importance of detailed records.

DISCUSSION.

Dr. C. P. Steinmetz said that the problem of lightning protection had become essentially an economic one, as to how far the cost of protective means was balanced by probable damage to apparatus. A protective device should be close to the apparatus to be protected, and it was a question whether we should not abandon altogether the attempt to protect distribution circuits, and confine attention to the apparatus connected to these circuits, installing the devices near them. In other words, it was becoming more economical from year to year to connect arresters to the device to be protected, and not distribute them along the line. Dr. Steinmetz described the manner in which the various data relating to lightning disturbances and abnormal voltages might be scientifically determined.

Prof. E. E. F. Creighton recommended, as a means for determining the condition of an aluminium lightning arrester, connecting an ammeter in series with it when it was being charged. The details of the method, however, were not elaborated. The valuable quality of an aluminium arrester was its capability of discharging heavy currents at abnormal voltages, but it could not economically be built to discharge the main generator current.

Mr. R. P. Jackson emphasised the importance of good insulation of apparatus. He did not believe in the indiscriminate use of lightning arresters that discharged freely, when they should be set to a higher voltage and the additional stress taken by the insulation of the apparatus. Some of the money that had been spent in protective apparatus might well be spent in better insulation and on improving the transmission lines.

Mr. Farley Osgood said there was a possibility in some cases of decreasing the number of lightning arresters now in use; but the lightning protection problem was one for individual study, as local conditions might influence the number of arresters to be used. Earthing the secondary would enable a reduction to be made in the number of arresters.

Mr. Percy H. Thomas agreed with Mr. Jackson as to setting lightning arresters at low voltage, as it was a menace every time an arrester discharged, the system being strained each time. A trouble to be expected with the electrolytic lightning arrester was that when the discharge passed over the horn-gap the potential of the line was momentarily reduced, and the apparatus subjected to a severe shock. The electrolytic arrester had the disadvantage over the multi-gap series arrester of discharging frequently. Numerous advantages of the multi-gap type of arrester were pointed out. Mr. Thomas said that the new schemes for shunting out an arcing earth on a transmission line seemed to have made progress. The idea of the type of device referred to was to close a circuit automatically in shunt at the power house as soon as the arc was established. This took the potential off that portion of the line, which then was automatically restored.

Mr. P. M. Lincoln said there were several means besides lightning arresters for taking care of lightning disturbances. One was the use of the suspension insulator, which had an earthed portion above the line to be protected; the second was the use of an earth wire above the transmission line, and the third was the earthing of the secondary distribution and primary transmission circuit. These three methods of construction would, he believed, secure a greater reduction in damage from lightning disturbances than the use of arresters.

Prof. Creighton considered some of the comparisons made between the aluminium and multi-gap arrester. The former, he said, was designed specifically to take care of continuous surges for a considerable length of time, which the latter could not possibly do, because of the heavy current that flowed and the high voltage expended in the resistance rods. When the neutral was earthed the difficulty was transferred from potential to current troubles. In many cases, however, it was advisable to earth the neutral, especially in the operation of a railway system.

Mr. E. J. Richards said that very good results had been obtained during the past two years from the use of aluminium-cell arresters on high-tension lines and feeders. He directed attention to the inspection and care required in the operation of aluminium-cell arresters. There had been only one interruption due to insulator failure on the lines referred to during the past two years, and this was caused by a direct stroke of lightning.

Mr. F. Osgood could not agree with the statement that multi-gap arresters required no attention, because dirt collected on them and would cause trouble if not removed.

Mr. H. L. Wills said that in the case of a 6,600-volt system good results had been obtained by connecting one side of the lightning arresters to the line and the other side to the earth wire; the next line was connected to a lightning arrester, but not connected to the same earth wire, &c. By connecting one lightning arrester to one line at one pole, and the next lightning arrester to the other line at another pole, there was a much easier discharge.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.: post free, 2s. 3d.

INNOVATIONS IN TRAMCAR CONSTRUCTION.

It is a common trouble on tramcars that the driver can not see easily what is taking place on the step of the car and consequently accidents occur over which he can have but little control. An attempt to overcome this difficulty is being made by the International Railway of Buffalo, U.S.A., and although the conditions there are not quite the same as in this country it may be worth while to call attention to the type of car which is there being introduced. As will be seen by the account given in another column the car is intended for use on what are called "street railways" in the United States. These railways work under conditions that apply in this country to tramways on the one hand and to light railways on the other.

The car is of the single-deck type and the entrance is at the front end only, there being two gates side by side, one for exit and the other for entrance. The driver is screened off from the car proper, but has full view of both these gates, which are on the same side of the car; he can therefore close them and start the car when he is certain that it is safe to do so. Although a conductor is provided the car is worked on the "pay-as-you-enter" principle, consequently the conductor has time to observe any signals that may be made to him and to call out the names of the streets. We doubt whether this mode of working would be acceptable in this country, but the main point of the construction is that the streams of incoming and outgoing passengers do not interfere with one another, and since the movements of the passengers entering or leaving the

Digitized by Google

car can be easily seen, accidents are avoided and there is greater ease of working. Passengers alighting can pass in front of a car of this kind instead of behind, and thus obtain a clear view of cars or other traffic approaching in the opposite direction, whereas such traffic is hidden from passengers passing behind in the usual fashion, and is thus a source of danger. The car in question has seats for 53 passengers and standing room for 30, the overall length being 45 ft. 2 in. The chief drawback seems to be that a car of this kind must always run in the same direction, and this involves a loop at the end of the line. A turntable might, of course, be used, but this would generally present serious objections. A loop, on the other hand, is extremely convenient for the handling of cars at the end of a line, particularly if the traffic is heavy, but it is not always easy to provide a terminus of this kind There should, however, be no great difficulty in making double-ended cars on the same principle by sacrificing a few seats.

Another type of car described in the present issue, and of interest owing to the special conditions involved, is that on which Edison accumulators are being used as a source of power. In an accumulator car the weight, and also any inefficiency due to friction, become of extreme importance, owing to the fact that a greater weight of battery must be carried to compensate for such defects. In order to give the Edison accumulator as good a chance as possible, the cars on which it is mounted have been constructed on somewhat different lines from those usually adopted. Thus, instead of having each pair of wheels fixed to a common axle, free running wheels are used, the axles themselves being fixed. No figure is given as to the precise saving in friction effected by this construction, but it is obvious that under certain circumstances the saving should be very considerable, and Mr. R. H. BEACH seems to have found it so in this particular case. Further, the usual gear drive has been replaced by a chain drive, as it is found that the efficiency of the latter is maintained longer at a high value than that of the gear drive, of which the efficiency suffers considerably by wear. The weight of the cars has also been reduced to a minimum. Whereas an ordinary single truck car weighs about 800 lb. per seated passenger and a double-truck car about 1,000 lb., the Edison-Beach double-truck accumulator car weighs per seated passenger only 600 lb., while a small single-truck car weighs 360 lb., the weight of the battery being 60 lb. per seat. The result of these alterations is that the energy consumption has been brought to a very low figure. Thus, in the case of a double-truck car, the consumption was 49·63 watt-hours per ton mile (presumably from the battery), whereas the consumption in the case of a double-truck trolley car would be something like 125 watt-hours per ton mile.

We do not suggest that all tramcars can be made correspondingly light; for the results obtained in such cases must be judged by the useful life obtained, and of that we have so far no information on which to go. We do think, however, that there is always a danger of working in a groove, and at the present time, when tramways generally do not pay as well as those who have control of them would wish, it might be worth while for the tramway engineer to look round and inquire whether present practice is necessarily all that is to be desired.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 2d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Three-Phase Transmission. By W. BREW. (London, 1911: Crosby Lockwood & Son.) Pp. viii. + 292. 7s. 6d.

In the preface the author tells us that he has omitted mathematics as far as possible, and that the few algebraical expressions he uses are of the most elementary character. Now there are two ways of avoiding mathematics. The one is by replacing the purely technical methods of the professional mathematician by the common-sense arguments of the engineer, and the other consists in simply skipping all mathematical investigation and introducing the result by some such phrase as: "It can be shown that the following formula holds good." Of the two, most readers would prefer the first method, but it becomes impossible with a subject of such complexity as the author treats in this book; he is perforce obliged to fall back on the second method. The result is not altogether satisfactory, since the reader has to take too much on trust. Take as an instance the expression given on page 20 for the capacity of a three-phase cable:—

$$K = 1{\cdot}5K_1 - 0{\cdot}166K_2,$$

where K_1 denotes the capacity of one core against the other two bunched together with the sheath, and K_2 the capacity between the three cores bunched and the sheath. Surely the reader may expect to be told in what way this formula is obtained. It is, of course, undesirable to burden the text of a practical treatise with mathematical arguments, but since a complex subject cannot be quantitatively treated without their help they might at least be given in footnotes.

Apart from the omission of such footnotes, the book is an admirable treatise on the technical and financial aspect of power transmission by three-phase current. The author never loses sight of the condition that engineering enterprise is only justified if it yields a financial profit, and he very justly insists that it is good policy to scrap old plant whilst still serviceable if by the substitution of new plant the profit on the total capital invested can be increased. This point, especially as regards transformers, cannot be too strongly insisted on. Manufacturers, consulting engineers and station engineers know quite well that it pays to scrap inefficient transformers and replace them with modern types; but, unfortunately, they cannot always convince the owners of the undertaking that it is good policy to buy new transformers. Mr. Brew shows that even a small improvement in hysteretic loss is, at present prices, sufficient to turn the scale in favour of a scrapping policy.

In Chapter I. we find a general survey of the whole subject, including tables of transmission plant now working in this country and abroad, life of plant, depreciation, repayment, covering interest and sinking fund, working pressure, drop and other characteristic features. According to the author, for transmission by cable, 20,000 volts over a maximum distance of 30 miles may be taken as reasonable limits; with overhead lines the corresponding figures are 110,000 volts and 300 miles.

In the second chapter the author discusses copper, dielectric, sheath and iron losses, and cites some experiments which showed a greater sheath loss with an unarmoured cable laid in cast-iron troughing than with the same cable armoured. In the first case the loss at $\nu = 50$ was 1·7 kw. per mile, and in the second only 1·3 kw., whilst with the unarmoured cable in air it was only 0·6 kw. As regards the most economical voltage, the author gives on p. 34 a table showing the cost per mile of a cable to transmit 1,000 kw. over distances of from 5 to 50 miles with a line loss of 2 per cent. It is remarkable that from 10 miles upwards minimum cost is obtained at a working pressure of 20,000 volts, and only for 5 miles is the lower working pressure of 15,000 more economical.

This subject of working pressure is further elaborated in the following chapter, especially in relation to annual cost, regulation, dielectric strength and corona effect.

After a descriptive chapter on control apparatus, the author

Digitized by Google

discusses impedance, pressure rise, higher harmonics, resonance, reflected waves, power surges and other complex phenomena; and, considering that he is doing so under the self-imposed handicap of higher mathematics being excluded, discusses it fairly clearly. Earthing and the effect of an accidental earth are treated in Chapter VI., whilst the constructive parts of an overhead line, both from a mechanical and electrical point of view, are treated in Chapter VII. In appendices are given the Board of Trade regulations for overhead wires, formulæ for self-induction and capacity, examples of line calculation and a comparison of transmission systems.

GISBERT KAPP.

Engineering Mathematics. By C. P. STEINMETZ. (New York, 1911: McGraw Hill Book Co.) Pp. xvii.+292. 4s. 6d. net.

This book gives a *résumé* of a series of lectures delivered by Prof. Steinmetz at Union College. The lectures were intended as an introduction to the study of the author's engineering works, and so special stress is laid on the methods which he employs. The book, therefore, is not a complete treatise on the subject and is not intended to displace the standard text books. As an introduction to the study of Prof. Steinmetz's Papers and books it can be recommended.

Recent developments in telephony and radio-telegraphy make a more thorough knowledge of mathematics essential to the engineer who desires to keep his knowledge up to date. This knowledge has opened up many fields of research. It gives to the engineer that perfect confidence in theory which is essential to the successful working out of many kinds of apparatus. Lack of this knowledge also, especially when combined with unlimited commercial push, is often a danger to the community as well as to the individual. In the reviewer's opinion, it is more than ever necessary that those engineering students who have the necessary talent be encouraged to widen the foundations of their mathematical knowledge so that this country may keep in the forefront of scientific development.

Many of the expressions in this book will seem quaint to the English reader. In explaining addition, for instance, we are told to add a "bunch of horses" numbering five to a "bunch" numbering three, and so obtain a "bunch" of eight. "Logarithmation" serves as an introduction to the quadrature number j. The old-fashioned phrase "equilateral" hyperbola is used instead of rectangular or equi-axial hyberbola. The method of "indeterminate coefficients" is an example of another old-fashioned phrase. If the coefficients are really indeterminate, surely the method is of no use, and if they can be determined then they are not indeterminate. It would be much better to call it the method of undetermined coefficients, or simply the method of coefficients. It is never advisable to use untruthful phrases.

In an appendix a useful introduction is given to the Theory of Functions. It is a pleasure to find the distinction between elliptic integrals and elliptic functions clearly stated and to have the doubly periodic nature of the latter pointed out. The gamma functions are described. On p. 274 we find the following line:—

"$0=1$; $\lfloor n=1\times2\times3\times\ \ldots\ \times n$."

Our sympathies are entirely with the junior student who has the sense to put $n=0$ in the second formula and then wonders why it does not agree with the first. As the author gives no help, he will naturally conclude that $0=0$, and that the 1 is a misprint. He will the more readily come to this conclusion as the number of misprints in this book is unexpectedly large. Hence he will be laying up for himself trouble in the future.

We think that the work would be very considerably improved and its value to the student greatly increased if the author gave references to Papers and books where the reader would find more detailed information on some of the functions described. For example, on p. 275 we were glad to find an elementary introduction given to the very important sine, cosine and logarithmic functions which are very rarely met with even in professedly pure mathematical books. Surely a statement that their numerical values have been tabulated by J. W. L. Glaisher in the "Phil. Trans.," London, 160, pp. 367-387 (1870) might save some budding radio-telegraphist days of dreary numerical calculation.

We are sorry that Bessel's functions have not been included. To the physicist in this country they are much better known than the θ functions. A description of Kelvin's ber and bei functions also would have been welcome, as they are required in two very fundamental electrical problems.

Tables of the values of ε^x, $\cosh x$, $\sinh x$, &c., are given to five decimal places, but in some cases we have found that the last figures are doubtful. It is easy to compute, for instance, the values of $\varepsilon^{\frac{1}{2}}$, $\cosh(\frac{1}{2})$ and $\sinh(\frac{1}{2})$. The reviewer makes them 1·64872, 1·12763 and 0·52110 respectively. The values given in the table are 1·64970, 1·12761 and 0·52108. To the engineer this may sound hyper-criticism, but the reviewer has spent so many hours in checking formulæ which he thought were inaccurate, as they gave results slightly differing from the tables, that he regards it as imperative that the last figure given in tables should be correct.

A. RUSSELL.

THE EXPRESSION OF RESISTIVITY OF ELECTRICAL CONDUCTORS.

BY J. H. DELLINGER.

Summary.—The author discusses the desirability of expressing resistivity as "mass resistivity" rather than volume resistivity, the chief reasons being that mass is more easily measured than cross-section and conductors are sold by weight rather than volume.

In THE ELECTRICIAN for March 17, 1911, there appeared an abstract of an article on the conductivity of copper,* by F. A. Wolff and the present author. In a summary preceding the abstract the editor states that in the article "several suggestions, including the expression of resistivity in ohms per metre-gramme, are made." The fact is that the article discussed and emphasised the advantages of using ohms per metre-gramme, but it was not the purpose of the authors to suggest a new unit, inasmuch as this unit is already in extensive use. Its advantages were appreciated a half-century ago, for Lord Kelvin, in "Phil. Mag.," Vol. XXIV., p. 156, 1862, says: "It is much to be desired that the weight-measure, rather than the diameter or the volume-measure, should be generally adopted for accurately specifying the gauge of wires used as electric conductors." Furthermore, Matthiessen, in 1865, gave his results of resistivity measurements of the metals in ohms per metre-gramme. The American Institute of Electrical Engineers in 1893 defined the standard resistivity from which their copper wire table was calculated in ohms per metre-gramme. The British Engineering Standards Committee define the standard resistivity of copper in terms of the resistance in ohms of "a wire 1 metre long, weighing 1 gramme." In this case the unit in question is used, although it is not given the specific name, "ohms per metre-gramme." Thus, we see that it is a well-established practice to express standard values of resistivity in ohms per metre-gramme. This unit is, moreover, established in commercial practice, at least for copper, as a number of the large electrical companies and copper wire manufacturers in the United States express the resistivities of wires in terms of it. Those who employ English units exclusively use "ohms per mile-pound" (sometimes called "pounds per mile-ohm"). This is exactly the equivalent of "ohms per metre-gramme," either unit being the product of resistance per unit length and mass per unit length, which is the definition of "mass resistivity." However, there are some persons who are not familiar with this unit, and some who do not think it is as desirable a one as the "volume resistivity"—*i.e.*, the resistance of a unit cube. A discussion of the subject, therefore, appears in order.

From the standpoint of the engineer and the user of conductors, especially line wires, the quantities directly concerned are the ohms, mass and length, rather than the ohms, cross-section and length; and the former are the quantities actually measured in the usual commercial and engineering tests of

* "Bulletin" of Bureau of Standards, Vol. VII., No. 1, p. 103.

Digitized by Google

copper. The measurement of cross-section or density is comparatively rare, and should be so, since the mass can be more easily and accurately measured. Accordingly, if the standard resistivity is defined in terms of cross-section, the result of the ordinary resistivity measurement expressed in terms of the standard will have different values depending on the density assumed. Thus, great confusion can arise in practice. From the practical standpoint, the "mass resistivity" combines two variables in one—viz., the "volume resistivity" and the density. To the purchaser of copper for conducting purposes it is equally desirable to have either the conductance 1 per cent. greater or the mass 1 per cent. less, and it is evident that either variation would affect the "mass resistivity" equally.

Since conductors are usually sold by weight, the relative commercial value to users of conductors of the same or even of different metals is given simply by multiplying the cost per unit mass by the mass resistivity. This statement of relative commercial value neglects differences in insulation, differences of stranding of cables, economy of space, &c. The reasons why the "mass resistivity" is preferable to the "volume resistivity" may be summarised, as in the Paper referred to above, as follows :—

1. The measurement of either cross-section or density in many cases is difficult and inaccurate.

2. The direct measurement of cross-section is practically impossible for irregular shapes of cross-section.

3. Conductors are sold by weight rather than by volume, and, therefore, the information of value to most users is given directly by the "mass resistivity."

Possibly one reason why the volume resistivity is still exclusively used by some people is the ease of defining it in terms of a unit cube. Such persons believe that their preference for volume resistivity over mass resistivity is due to the former's being more "scientific," whereas the real reason that they prefer it is because the mental picture of a unit cube is easy to retain. The opinion is here expressed that the worst thing about the unit, "volume resistivity," is the mental picture of a unit cube which accompanies it. Experience with students' examination papers has convinced the author that this conception too frequently leads to the gross error of thinking of resistance as proportional to volume. Indeed, practical men are often not careful to state "ohms per centimetre cube," so that we frequently read of "ohms per cubic centimetre." The resistance of a unit cube is not a practical case; wires are the usual articles whose resistance is desired to be known, and a form of expression of "volume resistivity" which fits the case better has been devised and is in extensive use. This form of expression is the "ohms per metre-millimetre" or "ohms per mil-foot," in which the greater dimension is the length of the wire and the smaller is the diameter. In these definitions we have the mental picture of a wire of a certain length and a certain diameter. When we speak of "ohms per metre-gramme" we have the conception of a conductor of a certain length and a certain mass per unit length. There should be no greater difficulty about the second conception than about the first, especially since the mass per unit length can be actually determined with greater ease and accuracy than the mean diameter.

It is to be noticed that the term "specific resistance" has not been used at all in this discussion. "Specific resistance" has been very extensively used in the past for the resistance of a unit cube. The term was, however, not well chosen, and seems to be tending to go out of use and give way to "resistivity." "Specific resistance" is considered to be an unfortunately chosen name for the resistance of a unit quantity because similar names—*e.g.*, specific heat, specific gravity, specific inductive capacity—refer primarily not to the property of a unit quantity of the substance, but to the ratio of the property of the particular substance to the same property of a standard substance. Another pedagogical stumbling block is found herein; for students are sometimes found defining "specific resistance" as the ratio of the resistance of some quantity of a metal to the resistance of the same quantity of copper. "Specific resistance" has probably not been much used for the resistance of a unit mass.

The term "resistivity" is a better name for the resistance of a unit quantity, just as "conductivity" is a better term than "specific conductance" would be. There is no *a priori* reason why "resistivity" could not refer to the unit mass, as some people profess to believe; and this term has not been limited to the idea of the unit cube historically. For example, as mentioned above, in the A.I.E.E. copper wire table the standard "resistivity" was given in ohms per metre-gramme. "Resistivity" is simply the property of unit quantity of a substance, and in defining it we are at liberty to choose any of the units of length, mass and time and the international electrical units. Since there are two modes of defining resistivity in common use, the unit mass and the unit cube, it is always desirable to indicate which is meant by using the precise expressions "mass resistivity" and "volume resistivity." These expressions are used in Alexander Russell's "Theory of Electric Cables and Networks," 1908. It may be worth remarking that no definition of resistivity is admissible which involves something not a property of the material itself. For example, we cannot speak of a "cost resistivity," since a unit whose value depends on business conditions cannot be considered a physical expression of the properties of unit quantity of a substance.

In the expression of "per cent. conductivity" there is a similar necessity for distinguishing between the definitions in terms of the unit mass and the unit cube. The term "per cent. conductivity" is extensively used in the copper industry, and on account of its convenience will probably continue in use. Of course, the per cent. conductivity can be calculated from either the mass resistivity or the volume resistivity, and if the density of the sample is different from the standard density these two per cent. conductivities will not agree. Accordingly, the use of "per cent. conductivity" should be limited to copper unless it is very carefully indicated whether it was calculated from the mass resistivity or the volume resistivity by the use of the terms "mass per cent. conductivity" or "volume per cent. conductivity." A striking example of the difference between the two per cent. conductivities in the case of a metal of different density from that of copper is furnished by aluminium. Thus, the "mass per cent. conductivity" of average commercial hard-drawn aluminium is 200 per cent., while the "volume per cent. conductivity" is 61 per cent. The general conclusion may be drawn from the foregoing that it is always desirable to state conductivity or resistivity directly in terms of the mass resistivity at a standard temperature rather than in terms of per cent. conductivity.

To sum up, this discussion has tried to show: (1) That "ohms per metre-gramme" is well established as a unit of resistivity, (2) that from a practical standpoint the "mass resistivity" is preferable to the "volume resistivity," (3) that the advantage of a mental picture to aid in defining volume resistivity is no less available in defining mass resistivity, (4) that "specific resistance" is an undesirable term, (5) that the term "resistivity" is susceptible of a certain breadth of definition, (6) that there are limitations to the proper use of "per cent. conductivity."

THE COMPARATIVE SENSITIVENESS OF SOME COMMON DETECTORS OF ELECTRIC OSCILLATIONS.*

BY LOUIS W. AUSTIN.

Summary.—The author describes some experimental comparisons of the sensitiveness of various wireless detectors including electrolytic, magnetic and vacuum valve detectors, a perikon detector being taken as the standard.

Although probably many comparisons of the sensitiveness of detectors have been made in the laboratories of the wireless companies, very little quantitative information on this subject has been made public. The difficulties usually encountered in laboratory tests are due mainly to the direct effect of the source of the oscillations on the receiving circuits and detector; but by using properly designed exciting circuits in connection with a buzzer as a source of oscillations these difficulties have been removed.

* Abstract of an article in the "Bulletin" of the Bureau of Standards.

Digitized by Google

Method of Experiment.—The exciting circuit in all the experiments is shown in Fig. 1. Here B is a buzzer run by two storage cells with considerable resistance in series. The oscillatory circuit consists of a variable air condenser, C_1, having a maximum capacity of 0·005 mfd., and for moderate wave lengths an inductance, L_1, of 0·062 millihenries. These are connected directly across the contact of the buzzer.

The action of the circuit is as follows : When the buzzer contact is broken, the condenser C_1 is charged and this charge is retained until the contact is again closed, when the condenser discharges through the contact, producing oscillations in the circuit L_1C_1. As these oscillations take place in a closed metallic circuit, they are very feebly damped unless extra resistance is introduced at R.

All buzzers are not equally suited to producing oscillations by this method. In some, considerable adjustment of the contact is required before sharp tuning is obtained. The buzzer used in these experiments was of the 1905 United States Signal Corps type, and gave very satisfactory results with wave lengths varying between 350 and 2,000 metres. With some care in adjustment the wave length could be pushed up beyond 3,000. For telephonic reception of signals it was usually found necessary to cut down the intensity of oscillations from the buzzer, and this was done by placing an incandescent lamp across the buzzer contact. The chalcopyrite-zincite rectifier known as the perikon detector was used as a standard for the comparison of the various detectors. As its sensitiveness varies somewhat from time to time, it was standardised before each experiment in the following manner, the circuits being shown in Fig. 2. Here I is the buzzer circuit, II a circuit containing a thermoelement of known sensitiveness, and III the circuit consisting of the perikon D, its coupling inductance L_4, and a suitable stopping condenser K of about 0·04 mfd. With a given loose coupling between L_3 and L_4 the relation was noted between the reading of the galvanometer attached to the thermoelement and that attached to the perikon, the condition of wave-length and damping being kept constant. This relation gives at once the relative sensitiveness of the perikon.

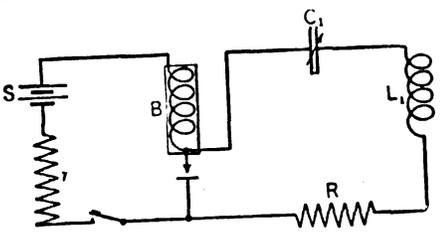

Fig. 1.

Two general methods have been used for measuring the sensitiveness for telephonic reception of radiotelegraphic receivers : First, the shunted telephone method in which the relative loudness of response to the same signal in two different receivers can be compared ; and, second, the variable coupling method by means of which the least audible signals for the different receivers can be compared.

Electrolytic Detector.—Comparison was made of the sensitiveness of the electrolytic detector and the perikon, using a wave length of approximately 900 metres and a decrement of the waves given out by the exciter circuit, amounting to 0·16. The values of the inductances and capacities of the circuits were so chosen that they simulated the conditions of commercial work. The perikon was used without external E.M.F. and also with about 0·2 volt applied in the direction of the rectification. Comparison was made by the shunted telephone method. Without external E.M.F. the perikon was found to be less than half (average 1/2·5) as sensitive as the electrolytic, but when 0·2 volt is applied the difference is very small, from 10 to 30 per cent in favour of the electrolytic. The electrolytic used was of the free-wire type and two positive Wollaston wires were used during the test, one 0·003 and one 0·0012 mm. in diameter. This was done because it has been frequently stated that the finer wire was more sensitive to weak signals. No marked difference between the two, however, could be detected.

A comparison of the galvanometer deflections with the thermoelement in circuit II and the intensity of signals in the electrolytic in circuit III, as measured by the shunted telephone method, showed that the responses of the electrolytic are proportional to the square of the oscillatory current.

Magnetic Detector.—The circuits for the comparison of the magnetic and perikon detectors are shown in Fig. 2. The magnetic detector was connected directly in circuit II, since it is usually used in the antenna. The magnetic detector employed was of the ordinary commercial type, the direct-current resistance of the oscillatory coil being 9·7 ohms and the telephone coil 120 ohms. For the comparison of sensitiveness the variable coupling method was used, the coupling L_1 and L_2 being changed until the signals became inaudible. When the readings on the magnetic were being taken the circuit containing the perikon was removed, then for the perikon readings the magnetic was cut out and the coupling L_3 L_4 regulated for maximum strength of signals. The relative strength of signals for the different degrees of coupling between L_1 and L_2 was determined by means of the deflection of a galvanometer attached to the perikon.

With waves from the buzzer circuit having a damping of 0·16 and a wave length of about 900 metres, it was found that the magnetic detector required 2·1 times as much energy to produce an audible sound as the perikon used without external E.M.F.

Further experiments showed that by putting a 0·05 mfd. condenser in series with the telephone of the magnetic, thus tuning it roughly to the rate of the buzzer, the loudness of signals could be increased so that there was very little difference between it and the perikon.

At a wave length of 3,000 metres the magnetic detector with tuned telephone was 1·5 times as sensitive as the perikon ; at 2,000 metres there was very little difference, whilst with waves of 350 metres the perikon was nearly five times as sensitive as the magnetic.

In order to explain these differences in relative sensitiveness, the logarithmic decrement of the circuit containing the magnetic detector was determined for various frequencies. The results indicated that the amount of iron and the number of turns of the oscillatory circuit of the magnetic detector should be varied according to the frequency for which it is to be used. The loudness of the signal in the telephone attached to the magnetic detector was found to be not proportional to the square of the oscillatory current, but more nearly to the 1·4 power.

Fleming Vacuum Valve Detector.—The detector tested was constructed with fixed coupling coils enclosed in its case, so that it was found impossible to test it fairly at any except very short wave-lengths without taking it completely to pieces. The circuits were arranged as shown in Fig. 2, the vacuum valve being coupled by its own coils to circuit II. At a wave length of 350 metres and with a decrement of the incoming signals of 0·16, the ratio of senstiveness of the perikon to that of the vacuum detector, as determined by the

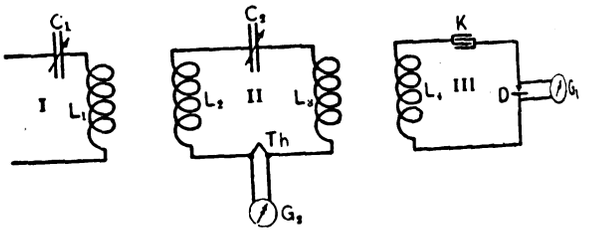

Fig. 2.

variable coupling method, was almost exactly two to one. For wave length of 900 metres the perikon appeared to be at least 1 times as sensitive as the vacuum valve. As there is no reason t believe that the vacuum detector would change its sensitiven with frequency, this difference is almost certainly due to insuffici coupling. The oscillatory energy in the main circuit was found to proportional to the audibility of signals in the telephone of vacuum detector.

The Audion.—The sensitiveness of the De Forest form of vacu detector, called by him the audion, was compared with that of t electrolytic already described by the varying coupling method. (Fig. 2.) The detectors were introduced alternately in circuit II and their most favourable conditions of coupling were determin separately. The audion, having a higher resistance, requires stronger coupling. The same telephones (1,200 ohms) were used both detectors, previous tests having shown that they were suited each. The energy sensitiveness of the audion was 1·5 times that the electrolytic. Some of the bulbs were slightly more sensit than this when first tried, but the sensibility decreased with use.

The law governing the relations between the intensity of the os lations and the loudness of response in the telephone, as determi by the shunted telephone method, seems to depend on the impres direct E.M.F. from the battery and also on the temperature of filament. For most adjustments the response of the telephon apparently nearly proportional to the square of the oscillatory curr

In addition to the above detectors, a very large number of ot types have been tested in the laboratory, including the tellur silicon and many crystal detectors. These are all of the rectify type and are remarkable in that when properly adjusted and with telephones of proper resistance, and in some cases with E.M.F. in the direction of the rectification, they all give practic the same sensibility as the perikon. The usefulness of severa these is, however, limited by the difficulty of adjustment and l of constancy. In most of these detectors the loudness of the sig increases nearly in proportion to the square of the oscillating curr although in some of them the increase in loudness is less rapid.

CORRECTIONS FOR THE EFFECTS OF ATMOSPHERIC CONDITIONS ON PHOTOMETRIC FLAME STANDARDS.*

BY W. J. A. BUTTERFIELD, F.I.C., J. S. HALDANE, M.D., F.R.S., AND A. P. TROTTER, B.A.

Summary.—The authors describe apparatus which they have used for determining the effects of variation of pressure, degree of humidity and atmospheric vitiation on the candle-power of the Harcourt pentane and the Hefner amyl-acetate lamps. As a result of these experiments, curves are given which go to show in the case of the Hefner lamp that Liebenthal's formula for corrections for barometric height does not rest on acceptable data. In conclusion, general correction formulæ for both lamps are given.

The effects of variation of the pressure, degree of humidity and vitiation of the atmosphere on the luminous intensity of flames cannot be determined from the variations naturally occurring in an ordinary photometric testing room, except perhaps by deduction from the data obtained in a very prolonged series of observations made with exceptional care concurrently with extremely accurate determinations of the composition of the air. The investigation may, however, be carried out in a much shorter space of time and with greater trustworthiness if the observations are made in a room or chamber provided with means by which one set of conditions may be varied at will to any desired degree almost or wholly independently of the other two sets of conditions.

The effects of variations in the atmospheric pressure on the light afforded by the Harcourt 10-candle pentane lamp, and by the Hefner amyl-acetate lamp, were first studied. For this portion of the work, and for some of the later investigations also, use was made of a steel compression chamber, designed primarily for physiological research on "caisson" disease or diver's palsy and mountain sickness. This chamber, which had been presented to the Lister Institute of Preventive Medicine by Dr. Ludwig Mond, F.R.S., was kindly placed at the disposal of the authors by Dr. Martin, the director of that institute. It is a short boiler of $\frac{5}{8}$ in. (16 mm.) plate resting on its side; the ends are slightly dished steel plates $\frac{1}{2}$ in. (13 mm.) thick. Inside it measures $7\frac{1}{2}$ ft. (2·29 m.) in length by 7 ft. in diameter (2·13 m.) and has a capacity of 336 cubic ft. (9,500 l.). In one end is an elliptical manhole 24 in. by 15 in. (609 mm. by 381 mm.), the cover of which is secured by large bolts and can be readily fixed or removed from outside the chamber. In addition to four spring valves, the chamber is provided with three simple valves by means of which the pressure can be completely controlled either from inside or outside. The pressure is raised or reduced by a simple compressor driven by a gas engine, and it can be raised when required at the rate of about 2 lb. per sq. in. (about 0·133 kg. per sq. cm.) per min. The circulation of air maintained by the pump was sufficiently rapid to prevent serious vitiation of the air of the chamber when two observers were present in it. The Harcourt lamp, when used, was placed below a hood directly connected with the outlet air-way from the chamber, so that the greater part of the products of combustion of the pentane did not mix with the air in the chamber before they were extracted from it. The efficiency of the ventilation of the chamber was checked by a determination of the proportion of carbon dioxide in a sample of the air taken while each set of photometric observations was in progress. These determinations were made by means of the portable apparatus for the determination of carbon dioxide in air devised by J. S. Haldane (*vide* "Journal of Hygiene," 1901, I., 109). In the subsequent investigation of the effects of atmospheric vitiation on the light afforded by the Harcourt and Hefner lamps, the proportion of oxygen in the air was also determined by means of the portable form of gas analysis apparatus devised by J. S. Haldane ("Journal of Hygiene," 1906, VI., 74). When necessary an electric fan was used in the chamber to keep the air well mixed. The chamber was provided with electric light and electric heaters, and telephone communicating with the outside. There were small stout glass windows in the ends. Two benches were arranged in the chamber. On one of them the photometer, with an electric standard lamp and the flame standard, was set up, while the other was used for the air-analysis apparatus and accessories. The degree of humidity of the air was ascertained by means of an Assmann hygrometer (*vide* "Zeits. für Instrumentenkunde," 1892, XII., 1) which consists broadly of wet and dry bulb thermometers, over which a regulated current of air is drawn by means of a clockwork fan. A simple U mercury manometer, one limb of which communicated with outside, was used for measuring pressures above normal, and the pressures below normal were read on a standard mercury barometer inside the chamber.

A small electric lamp was used as a standard. It was mounted on a carriage guided by V notches. A rod attached to the carriage, as in the Gas Referees' photometer, was used to adjust the position of the lamp. A scale was carried on the rod, and an index was fixed to the photoped. The filament of the lamp was carefully set and this setting was inspected from time to time, but after about 20 sets of observations had been made it was found that the filament had warped, and that the warping was introducing an uncertainty of about 2 per cent. in the later sets of observations of the first series. An Osram lamp intended to give 10 c.p. at 10 volts was tried, and was supplied by six accumulators controlled by an adjustable resistance. But a comparison with the pentane lamp showed that the colours of the lights differed too widely to make accurate photometry possible until the light of the electric lamp had been reduced

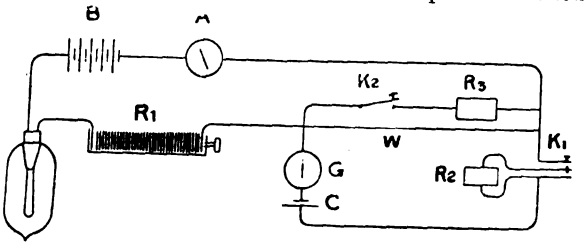

FIG. 1.—DIAGRAM OF ELECTRICAL ARRANGEMENTS.

to about 1 c.p. It was hoped that a metallic filament lamp thus used would have an enhanced "life," or, in other words, would vary less by ageing than if worked at 10 c.p. But the result was disappointing. It might have been better if the lamp had been worked at a constant pressure; but with the view of eliminating the effects of imperfect contacts, adjustment was made for working at a constant current. Another defect in the arrangement was the use of the electric lamp with the filament erect instead of hanging downwards. Notwithstanding the low candle-power at which it was worked, the filament warped as has been mentioned.

The arrangement used is shown in Fig. 1. The lamp L was supplied with current from the five-cell battery B, the circuit was completed through an adjustable rheostat of carbon plates, R, a manganin wire, W, of about 1·54 ohms resistance, and an ammeter, A. In parallel with the wire W, a circuit contained a reflecting galvanometer G, a Weston cadmium cell C, and a double key, K_1. A light pressure of this key completed the circuit through the high resistance R_2, which saved the cell from injury in case the lamp circuit was not completed. When an approximate adjustment of the current to 0·66 amp. had been made, the key was pressed hard down and kept closed. Another circuit contained a resistance of 1,000 ohms, R_3, and a key, K_2. When the current was adjusted and the galvano-

Digitized by Google

meter G indicated zero, closing K_2 gave a deflection corresponding to 0·35 per cent. difference of current. The current, as a rule, was kept steady within about one-tenth of this amount. In the second series of experiments, a large battery being available, a Fleming-Ediswan photometric lamp standard was used, giving 10 c.p. at 60·05 volts with 0·7577 amp. This gave no difficulty. The lamp holder was double-wired, and the volts were measured with a potentiometer.

The experiments made to determine the corrections for variations of atmospheric pressure were all carried out in the steel compression chamber described above. The range of variation of pressure for the observations was from about 450 mm. to 1,000 mm. (or from about 17¾ in. to 39½ in.). The results of the observations were ultimately corrected for the variations in the proportions of aqueous vapour and of carbon dioxide in the air (according to formula referred to later) and the corrected figures thus obtained were plotted and give the curves shown in Fig. 2. The curves show that the relation between atmospheric pressure and the yield of light is not constant or expressed by a straight line. The falling-off in the light with reduction of pressure is much greater at the lower than at the higher pressures.

The curve for the Harcourt lamp is, however, nearly a straight line for the range of 700 mm. to 850 mm., and shows that within these limits the light increases or decreases by 1 per cent. with an increase or decrease respectively in pressure of 12·5 mm. or that a variation of 10 mm. in pressure is attended by a variation in the same sense of 0·8 per cent. in the light afforded by the lamp. These figures agree exactly with the correction deduced by C. C. Paterson ("Journal" Inst. of Electrical Engineers, 1907, XXXVIII., p. 280), which may, therefore, be accepted as correct for variations of pressure at about the neighbourhood of normal. In regard, however, to the effect of variations of pressure elsewhere, the authors

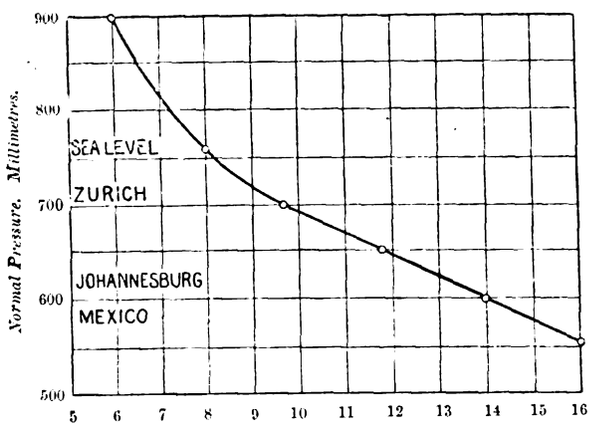

FIG. 3.—CURVE OF CORRECTION FACTOR.

have failed to find a rational equation to the pressure curve for the Harcourt lamp, and prefer to give the curve of the differential coefficient (shown in Fig. 3) rather than an empirical formula. By the use of this curve, the correction which should be applied to the Harcourt lamp for barometric variations at any place at which the mean barometric height is considerably below 760 mm. may be deduced.

The curve for the Hefner lamp is likewise nearly a straight line for the range of 700 mm. to 850 mm., and shows that within these limits the light increases or decreases by 1 per cent. with an increase or decrease respectively in pressure of 25 mm., or that a variation of 10 mm. in pressure is attended by a variation in the same sense of 0·4 per cent. in the light afforded by the lamp. These figures differ from the correction deduced by Liebenthal from observations of the variation of the light of the Hefner lamp caused by the natural fluctuations of the barometer between 735 mm. and 775 mm. Liebenthal has adopted a formula according to which a variation of 10 mm. in pressure is attended by a variation of only 0·1 per cent. in the light. ("Zeits. für Instrumentenkunde," 1895, XV., 157, and "Praktische Photometrie," p. 121.) Paterson mentions that he found for 10 mm. variation in pressure 0·2 per cent. variation in the light. The authors have therefore found that, about the neighbourhood of normal, variation of pressure has only half the effect on the light of the Hefner lamp which it has on that of the Harcourt; but, on the other hand, that it has on the Hefner lamp four times the effect shown by Liebenthal's formula, which has been very generally accepted. The facts that the effect of small barometric changes, such as Liebenthal had available, is small compared with the effect of the unavoidable changes in the proportions of aqueous vapour and carbon dioxide in the air, and that the proportion of the latter was not ascertained by Liebenthal, indicate that his formula for the corrections to be applied to the Hefner lamp for variations of barometric height does not rest on acceptable data. The authors ascertained the proportions both of aqueous vapour and carbon dioxide in the air during the observations, and applied corrections to eliminate their effects, while the greater range of barometric change which they had at their disposal reduced the effect of unavoidable errors of observation on the final result. For these reasons, they believe that their figure of 0·4 per cent. should now be accepted in preference to Liebenthal's 0·1 per cent. for the effect on the light of the Hefner lamp of a change of 10 mm. in barometric pressure in the neighbourhood of 760 mm. In regard to the effect of variations of pressure in other regions of the barometric scale, the curve found by the authors coincides fairly well with the results of observations made by Liebenthal in a pneumatic chamber, in which results, however, he appears to have placed but little reliance because of the presence of a number of disturbing factors.

The experiments made to determine the effect of variations in the humidity of the air on the light afforded by flames were carried out partly in the steel chamber already described and partly in a small room at the Electrical Standards Laboratory of the Board of Trade at No. 8, Richmond-terrace, Whitehall, London. This room was 4·03 m. (13 ft. 2¾ in.) long, 1·975 m. (6 ft. 5¾ in.) wide, and 2·45 m. (8 ft. ½ in.) high. There was no pump for renewing the air of this room, but a hood attached to a flue-pipe passing through the wall of the room was placed over the lamp, the heated products from which created a strong draught through the flue-pipe. The proportion of aqueous vapour in the air was increased as required by passing steam into the chamber or room from a small boiler placed outside it. A large range in the proportion of aqueous vapour in the air was secured by choosing dry, cold days, on which observations of the light of the lamps when the humidity was low could be made. The chamber or room having been heated by electric heaters, the air was then nearly saturated with steam at the high temperature. The range of humidity thus secured was from about 1 per cent. to over 4 per cent. by volume of aqueous vapour in the air. Sets of observations on the Harcourt lamp showed that a change in the temperature *per se* of the air from 8°C. to over 20°C. had no definite effect on the light afforded. The steam introduced was well disseminated in the air of the chamber or room by means of an electric fan. In one set of observations, greater initial dryness of the air was secured by exposing trays of granulated calcium chloride in the room for 12 hours, while circulation of the air over the trays was maintained by the fan. The results of observations were in all cases corrected for variations in the barometric height and in the proportion of carbon dioxide in the air. The results showed that the light of both the Harcourt and Hefner lamps decreases by 1 per cent. for an increase of 0·16 per cent. in the aqueous vapour in the air or that an increase of 1 per cent. in the aqueous vapour in the air is attended by a decrease of 6·25 per cent. in the light of the lamps. Liebenthal found 5·5 per cent. for both lamps ("Zeits. für Instrumentenkunde," 1895, XV., p. 157, and "Praktische Photometrie," pp. 118 and 128), while Paterson has found 6·6 per cent. for the Harcourt and 6·0 per cent. for the Hefner lamp ("Journal" Inst. Electrical Engineers, 1907, XXXVIII., pp. 276, 277) as the decrease in the light caused by 1 per cent. increase in the aqueous vapour in the air.

Experiments made to determine the effect of different degrees of vitiation of the atmosphere on the light afforded by flames were made on air vitiated, partially by breathing and partially by the combustion of pentane or illuminating gas. The ratio of carbon dioxide produced to oxygen consumed differs according to the composition of the fuel consumed, and the composition of vitiated air will therefore differ according as the vitiation arises wholly or mainly from breathing, from the combustion of a hydrocarbon body such as pentane, or of the mixture of a number of combustible gases, in which hydrogen predominates, which constitutes ordinary town illuminating gas. In the experiments made by the authors, the proportions of both carbon dioxide and oxygen in the vitiated air were determined by analysis, and the somewhat complex results obtained will be dealt with more fully in a subsequent communication. But taking the proportion of carbon dioxide in the air as the sole measure of vitiation caused partially by breathing, but mainly by combustion of paraffin hydrocarbons or town gas, it was found that 1 per cent. decrease in the light of the Harcourt lamp was caused when approximately 0·035 per cent. of carbon dioxide was present in the air, and in the light of the Hefner lamp with 0·04 per cent. Or the presence of 0·01 per cent. of carbon dioxide in the air was attended by a reduction of 0·29 per cent. in the light of the Harcourt, or of 0·22 per cent. in the light of the Hefner lamp. In the experiments on which these figures for the Harcourt lamp are

Digitized by Google

based, the proportion of carbon dioxide in the air ranged from 0·09 per cent. to 2·54 per cent., and of oxygen from 20·80 per cent. to 17·40 per cent. With 2·54 per cent. of carbon dioxide and 17·40 per cent. of oxygen, the flame of the Harcourt lamp was blue and practically non-illuminating. The diminution in light is fairly uniformly proportional to the increase in the amount of carbon dioxide up to about 2 per cent. of the latter—*i.e.*, the curve given by the figures is nearly a straight line to that point. The experiments on the Hefner lamp were not made over so wide a range as those on the Harcourt lamp.

The corrections found for the Harcourt and Hefner lamps may be applied thus:—Let A be the accepted normal percentage of aqueous vapour in the air, C the accepted normal percentage of carbon dioxide in the air, P the accepted normal pressure of the air in millimetres, *a* the prevailing percentage of aqueous vapour in the air when the lamp is in use, *c* the prevailing percentage of carbon dioxide in the air when the lamp is in use, *p* the prevailing pressure of the air when the lamp is in use, then the actual light (I′) of the lamp at the time, expressed in terms of its light (I) in normal conditions will be found with sufficient accuracy for all practical purposes from the equations. For the Harcourt lamp:—

$$I' = \frac{100 - \left(\frac{a-A}{0{\cdot}16} + \frac{c-C}{0{\cdot}035} - \frac{p-P}{12{\cdot}5}\right)}{100} I.$$

For the Hefner lamp—

$$I' = \frac{100 - \left(\frac{a-A}{0{\cdot}16} + \frac{c-C}{0{\cdot}045} - \frac{p-P}{25{\cdot}0}\right)}{100} I.$$

The results obtained in the observations made on the flames of the No. 2 "Metropolitan" argand, and the Bray $\frac{\text{"C"}}{L}$ 5 ft. $\frac{15}{10}$" slit flat-flame gas burners, when consuming the gas supplied in Chelsea and Westminster by the Gas Light & Coke Co., and on the flame of the English Parliamentary standard spermaceti candle, must not be accepted as so trustworthy as those given for the Harcourt and Hefner lamps because they are based on fewer observations. These results are therefore given with reservation in the following tabular statement:—

	1 per cent. decrease of light is caused approximately by the following changes from normal:		Vitiation expressed by $\%CO_2$.
	Pressure.	Aqueous vapour.	
No. 2 Metropolitan argand gas	−2·5 mm.	+0·20 per cent.	+0·03 per cent.
Flat-flame gas	−5 mm.	+0·11 ,,	+0·035 ,,
Spermaceti Candle	−20 mm.	+0·50 ,,	+0·04 ,,

These results indicate that small variations in the atmospheric conditions of a gas-testing room will not appreciably affect the results of photometric comparisons in which the Harcourt or Hefner lamp is used as the standard of light, and that these standards will give as accurate results as are anyhow practically obtainable in determinations of the illuminating power of gas if they are used in all ordinary circumstances without correction for any divergence from normal atmospheric conditions. In other circumstances, however, as in the testing of electric lamps by a flame standard, corrections are called for.

THE EFFECT OF POWER FACTOR AND LOAD FACTOR IN ELECTRIC FURNACE WORK.

BY J. HÄRDÉN.

In addition to being affected by frequency the power factor of an induction furnace is also affected by the design, and may be improved by shortening the diameter of the secondary winding—*i.e.*, the melting chamber—as the space for the leakage field is thereby reduced. But apart from the danger of thinning the lining too much, this has not such a great effect as one might expect, as the resistance is thereby lowered, because of the shorter circumference of the ring. For this reason some inventors have patented hearths of strange shapes, forming an oblong loop, &c., but the practical man is generally content with the simplest shape—*i.e.*, the ring—in spite of all power factors. Shields for checking the leakage field are also being tried, but are generally found to be too complicated.

The simplest solution seems to be the combined or Roechling-Rodenhauser type of furnace, where the auxiliary secondary winding is in close proximity to the primary, thus effectively checking the stray field. This has enabled the furnace builder to design such furnaces in sizes up to 16 tons, while the plain induction furnace works best in capacities of 1 to 3 tons.

The metallurgist is more familiar with the term load factor than with power factor. The fluctuations of the load are particularly noticeable in the case of arc furnaces where the whole power is converted into heat by means of one or two arcs in series, playing between the steel and the electrode. Owing to the larger amount of power which has to pass over a distance of, say, 1 in. to 2 in., and confined to an area of 200 sq. in only, the gases in this space are highly superheated, and will therefore expand violently, acting, in fact, as a strong blowpipe. The result is that the slag is driven out from beneath the ends of the electrodes, leaving the metal bare. In consequence of the high temperature on these spots, a strong boiling action of the steel can be observed; the steel is strongly agitated and touches the electrode frequently, causing a momentary short-circuit, especially when charging cold material. The current will, therefore, fluctuate between 0 and 35 to 45 per cent. overload.

It will be of some interest to compare the effect of power factor and load factor upon the first cost of an installation of arc and induction furnaces and also upon the operating costs. Dealing first with the induction furnace and the lower power factor, *or else lower frequency*, for a furnace of, say, 5 tons capacity under extremely bad conditions, we find $\cos\phi = 0{\cdot}55$ at 10 cycles, and $\cos\phi = 0{\cdot}13$ at 50 cycles; and we shall assume that the practical rule is correct, which says that the weight of a generator for a given kilovolt-ampere output is in about inverse proportion to the speed and the square root of the frequency. In such a case, as O. Zander has suggested, it would be economical to compensate the power factor by operating synchronous motors for other purposes in parallel with the furnace generator. Under these conditions the weights (and thereby the costs) for the aggregates would be as follows:—

Assuming that "A" is the actual weight of a generator, built at 50 periods, and a power factor of $\cos\phi = 1$, then the weight X of other generators will be:—

1. For a generator for 10 periods and $\cos\phi = 0{\cdot}55$,

$$X = \sqrt{5} \cdot \frac{1}{0{\cdot}55} A = 4{\cdot}048 A.$$

2. For a generator at 10 cycles and $\cos\phi = 1$, together with one synchronous motor for 10 cycles and double the speed of the generator, the weight

$$X = \sqrt{5} \cdot A \cdot \frac{\sqrt{5} A 1{\cdot}52}{2} = 3{\cdot}94\ A.$$

3. For a generator at 50 cycles and $\cos\phi = 1$, together with one synchronous motor for 50 cycles and 10 times the speed, the weight

$$X = A \cdot \frac{17{\cdot}6\ A}{10} = 1{\cdot}76\ A.$$

The reduction of the weight may be even greater, because one can, as is well known, run a 50-cycle generator at a greater speed than one for 10 cycles. If the energy is supplied from a distributing system of 50 cycles only one high-speed synchronous motor is required instead of a heavier low-speed motor-generator, as is commonly used at the present time. As a rule, however, such extreme conditions need rarely be reverted to, as the Roechling-Rodenhauser furnace shows a much higher power factor.

To compare the actual prices of generators to suit normal conditions, the following quotations were obtained from one of the leading European electrical firms, viz.: The conditions were to operate either a Roechling-Rodenhauser furnace for 10 tons at 10 and at 25 cycles or an arc furnace of the same capacity. The prices were as follows:—

For Induction Furnaces.			
(*a*) One generator for 3,000 volts 25 cycles 1,000 kw. power factor 0·6	£1,900	0	0
(*b*) One generator for 3,000 volts 10 cycles, 1,000 kw. power factor 0·85	£2,280	0	0
For Arc Furnaces.			
(*c*) One generator, 3,000 volts 25 cycles 1,000 kw. power factor 0·85 to 0·09, provided with such arrangements as to suit arc furnace conditions (transformer not included)	£1,800	0	0

The difference in price for the arc furnace generator and that for the induction furnace generator is, as will be seen, only slight. If we consider that the induction furnace can be operated direct with high pressure up to 5,000 volts, while the arc furnace requires only about 100 volts, so that a transformer will be generally necessary, the difference in price will be even more insignificant, although it is true that the transformer is already built in, forming part of the induction furnace. Against this it must be remembered that the prime mover in the case of an arc furnace plain and simple must be far more substantially built, and therefore more expensive than for an induction furnace, in order to stand the sudden current fluctuations.

As to the cost of operation of both systems, it should be remembered that in the case of the induction furnace only the actual kilowatt-hours have to be paid for. It is true that a supply company will incur a somewhat higher charge for the current if the power factor is lower than 0·90, but as a "peaky" load will be charged for

Digitized by Google

at a considerably higher rate than a steady load, the difference in running costs should not show much difference.

Conclusions.—Taking all the above statements into consideration, it is quite clear that from the electrical engineer's point of view, apart from the requirements of metallurgists, neither the induction furnace, as such, nor the plain arc furnace work under ideal conditions, the former because of its lower power factor and the latter for the reason of its unsteady load. Therefore, a furnace so designed as to combine the good features of both—*i.e.*, the higher power factor of the arc furnace and the high and steady load-factor of the induction furnace—would undoubtedly be very desirable, and it stands to reason that such a solution of the problem would be welcomed by the metallurgist as well, provided the design be simple and reliable. Then to convey all the energy of a large furnace, say, for 15 or 30 tons capacity, to the bath by means of electrodes only appears to be rather difficult if we consider that a 15-ton furnace for three-phase current requires electrodes about 26 in. square. Such electrodes are very difficult to obtain, and the maintenance of the roof is no easy task under such conditions.

Again, a combined furnace for 16 tons can be and, in fact, has been designed, but there are many metallurgists who maintain that a higher temperature should and must be applied from above the bath. Hence, a furnace showing the above-mentioned features certainly appears to be desirable. It may perhaps be of interest to mention that a furnace of this kind is now under design, but owing to pending patent applications the description of the same must be deferred to a later date. [Since writing the above these patents have been granted, and are embodied in the "Paragon" furnace referred to previously in this Paper, which furnace has been designed on the above principles by the author.]

THE CAUSES OF ZERO DISPLACEMENT AND DEFLECTION HYSTERESIS IN MOVING COIL GALVANOMETERS.*

BY ANTHONY ZELENY.

Summary.—In a moving coil galvanometer the displacement in the zero reading which takes place after a first deflection has generally been ascribed to a true set in the suspension fibre. The investigations here described prove this view to be erroneous and that practically the whole effect is due to the action of magnetic impurities within the coil.

Zero Displacement after a Deflection.—A galvanometer coil, G, was suspended within a wooden frame between the poles of a large electromagnet as shown in Fig. 1. If the zero displacement is due

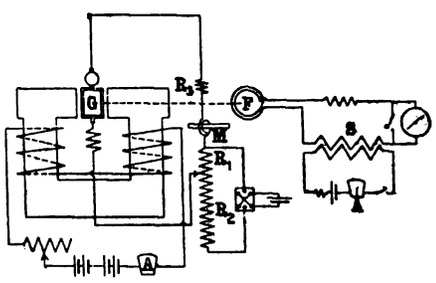

FIG. 1.

to a true set in the fibre its magnitude after reversed deflections of equal size would be independent of the intensity of the magnetic field, but if the effect is due to magnetic impurities within the coil the magnitude of the displacement would increase with the intensity of the field. The deflecting current was varied so as to produce the same deflection with each altered intensity of the field. In all cases the coil was made to move aperiodically to its deflected position as well as to its zero or null reading, in stronger fields by placing the proper resistance in R_3 of the galvanometer circuit and in weaker ones by induced currents from an accessory coil and magnet M. The intensity of the field was measured by jerking the test coil F through the field by means of a spring and comparing the ballistic galvanometer throws with those obtained from a standard inductance coil S. The test coil had the same area as the pole pieces and measured the intensity of the field in the immediate neighbourhood of the poles. The galvanometer coil G was at some distance from the poles, and the intensity of that part of the field containing it was obtained by multiplying the values given by the test coil by the approximate, experimentally determined factor 0·768.

The galvanometer coil was taken from a Leeds and Northrup galvanometer, and was the one of several tested that contained the smallest amount of magnetic impurities. The coil is a hollow rectangle, 2·05 by 5·1 cm., and has a mass of 6·66 gms. and a moment of inertia of 3·49 C.G.S. units. The upper suspensions employed were of phosphor-bronze strip and the lower suspension was an ordinary 1·5 mil phosphor-bronze strip spiral of 7·5 turns.

The observations for the zero displacement of the coil for any particular field intensity were taken at equal intervals of one minute, after several successive deflections alternating in direction. The zero displacement after the first reversal was always considerably larger than that observed after the following ones which gave nearly equal though consistently diminishing values. The displacement of the null reading in fields of different intensity, when using the 3 mil upper suspension and reversing the current from a deflection of 20 cm., is given in Curve A, Fig. 2, the displacement after the first reversal being discarded and the average of the following three taken. It is observed that in fields whose intensity is less than 100 the displacement curve is nearly horizontal, and the point where it cuts the axis of ordinates represents the amount of displacement due to a true set in the suspension fibre. This, however, is so small that under ordinary conditions of use it would rarely be observable. Under the conditions given, the true set in the fibre is represented by a displacement of 0·015 cm., while the zero displacement in a field whose intensity is 400, such as is common in ordinary galvanometers, is 0·26 cm. With this coil and suspension, less than 6 per cent. of the observed zero displacement in a galvanometer is due to a true set in the suspension fibre and more than 94 per cent. to the magnetic hysteresis within the coil.

With a 1·5 mil phosphor-bronze strip suspension the zero displacement, under the same conditions as above, gave in the weakest

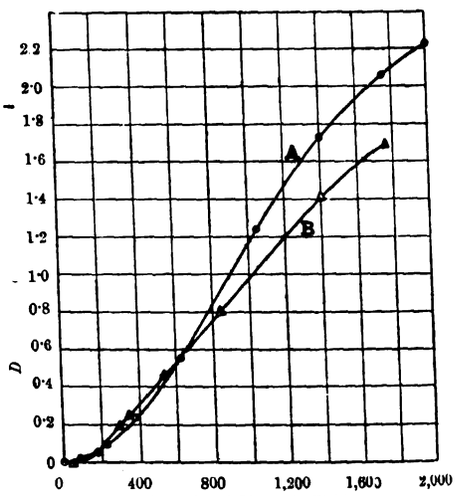

FIG. 2.

field a displacement not exceeding 0·005 cm., or one-third that obtained with the 3-mil strip. It is seen, therefore, that the larger zero displacement observed in galvanometers with the thinner suspensions is due entirely to the magnetic properties of the coil and not at all to a greater set in the fibre. The magnitude of the torsional moment of the suspension practically alone determines the amount of the zero displacement for the same alteration in the magnetic moment produced by the reversal.

The results of a set of observations taken with a 1·5 mil phosphor-bronze strip suspension are plotted in curve B of Fig. 2. In this case the reversals were taken from a deflection of 15 cm. in place of 20; and the distance of the scale was 125 cm. in place of 54·5 cm. for Curve A. The zero displacement in the weakest field was too small to be observable, and, therefore, no appreciable set existed in the suspension fibre in any of the displacements observed.

The magnetic moment due to the magnetism in the galvanometer coils was found to differ considerably, even in instruments of the same type and manufacture, varying from 0·129 to 0·217 C.G.S. units.

Deflection Hysteresis.—In a former Paper* on "Precision Measurements with the Moving Coil Galvanometer," the writer observed that deflections of different magnitude were obtained with the same current, depending on whether they reached their value from a larger or a smaller one. This was explained as due to a change in the intensity or direction of magnetisation of the impurities within the coil. In order to account for the observed changes, it was necessary to assume that the coercive power of the magnetic impurities was very large. To prove, experimentally, that this is so, the

* Abstract of an article in the "Physical Review."

* Physical Review," Vol. XXIII., p. 401, 1906.

Digitized by Google

values of M/T (M=magnetic moment due to action of field on impurities, less diamagnetic effect on copper; and T=torsional moment) were now obtained in various fields with the intensity increasing to a maximum and then decreasing. The hysteresis curve obtained, when using a 3 mil suspension fibre, is plotted in Fig. 3. The coercive power is found to be sufficient to account for the observed deflection hysteresis. It will be seen, also, that the upper bends in the curve begin, as should be the case, in a field of the same intensity as the upper bends of the zero displacement curves in Fig. 2. These bends occur in a field whose intensity is more than 200 times that which produces the same effect in the case of iron. The stray magnetism was found to have no appreciable effect upon the torsional moment of the suspension fibre.

An investigation of the change in the damping factor with the intensity of the field showed that in field intensities of 400, common to galvanometers, when the coil is on open circuit, the damping due to the induced currents is less than 50 per cent. of that due to the resistance of the air and the internal friction of the fibre, or only about one-third of the total.

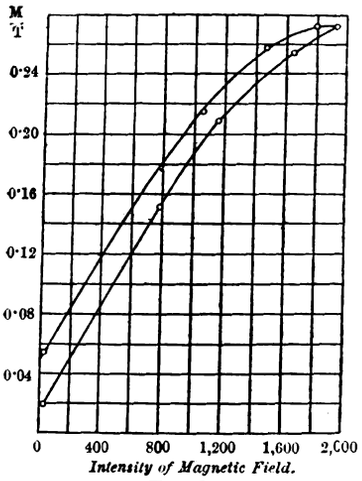

FIG. 3.

The sensibility of the galvanometer formed by the electromagnet and the coil was found, as expected, to increase at a smaller rate than the intensity of the field. The current for 1 mm. deflection being $1{\cdot}53\times10^{-8}$, $0{\cdot}84\times10^{-8}$ and $0{\cdot}7\times10^{-8}$ for fields of intensity 445, 932 and 1,315 respectively.

AN IMPROVED TRAMCAR LIFEGUARD.

The proper design of devices for protecting people who may fall in front of trams from serious injury is a question highly deserving of attention by tramway managers. However careful a foot passenger

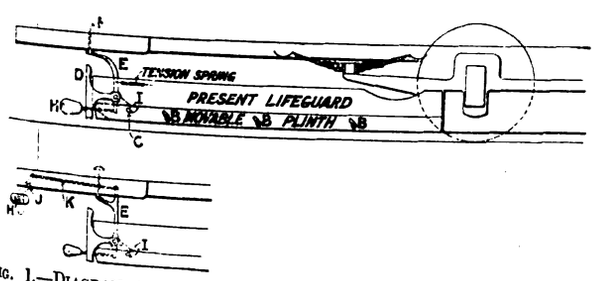

FIG. 1.—DIAGRAM SHOWING THE IMPROVED LIFEGUARD FITTED TO A TRAMCAR.

may be in crossing the streets of a crowded town (and he does not generally err unduly in this respect), or however attentive the driver may be, collisions are sometimes inevitable. This being the case, it is necessary that some guard should be provided to prevent the unfortunate person who is knocked down from being enmeshed in the wheels, not only for his own sake, but because such a catastrophe must necessarily lead to traffic delays.

Many excellent arrangements have been designed with this end in view, and by the Board of Trade regulations some such device must be carried on every car. The plough lifeguard has been associated with the Liverpool tramways for some years, and it has been found satisfactory. With the idea of making it more perfect Mr. C. W. Mallins, general manager of the Liverpool Corporation Tramways, has designed an attachment which he hopes will have the effect of still further reducing the number of fatal accidents. Its object is to close the space that at present exists between the plough and the ground.

This device, which is illustrated in Fig. 1, consists essentially of two movable plinths which are attached by screws and studs, B, to each side of the plough lifeguard. These studs are free to move in slots cut in the plinth. The plinths are held in their normal out-of-action position—that is, with the studs at the bottom of the slots—by means of the lever E. This lever turns round a pivot which carries the nose, D, that holds up the plinths. It has three arms. The first is hooked at its extremity so as to form a catch which engages with the cross stay, C, connecting the plinths. The second lever, E, mentioned above, releases this catch when necessary, being operated by a foot-punch, F, on the driver's platform. On depressing this punch the catch, I, is raised and the plinths and nose fall to the ground, the studs, B, rising to the top of the slot. When the pressure is released the lever is returned to its normal position by a spring. The third lever abuts against the stem of the radial buffer, H, on the front of the car, so that when any obstruction strikes the latter the catch is released and the plinths are allowed to fall, thus closing the aperture between the plough and the ground. The plinths can alternatively be released by means of a Bowden wire leading down from the controller top. By threading the shank of the arm, I, and making it adjustable, the distance between the lower edge of the plinths when in upper position and the ground can be kept constant as the wheels wear away. The lower edges of the plinths are provided with rubber belting or piping which takes up the shock. We understand that experiments made with a dummy on this arrangement have given the highest satisfaction.

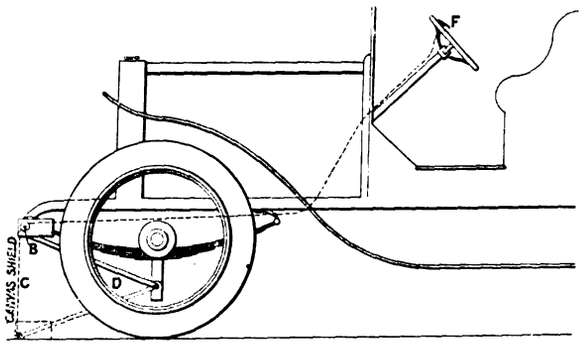

FIG. 2.—THE LIFEGUARD FITTED TO A MOTOR 'BUS.

The same idea has also been applied to motor omnibuses (*see* Fig. 2). A light angle iron frame slightly curved at the extremities, is mounted on the dummy iron. Attached by spring eye-bolts fixed to the underside of this frame by short brackets is a steel spring roller, B, carrying a strong canvas shade (or shield), C, the lower edge of which is fastened to an angle-iron frame similar to the first. The arms D are attached at one end to the lower frame and at the other to the axle-tree, and take the thrust when the guard is in operation; a locking catch holds the lower frame up in position, and is released by means of a Bowden control operated from the steering wheel. In operation the driver depresses the thumb lever, F, which draws back a catch, and allows the lower frame to fall to the ground, and in so doing unwinds the shade, or shield, from the roller, thus preventing any injury to the person in front of the car. This device has been applied to the motor omnibuses running to Woolton, which hitherto have carried no such safeguard. A similar arrangement would not be out of place in London.

COLLIERY POWER PLANT: A COMPARISON OF GAS AND EXHAUST STEAM.*

BY JOHN BURNS.

All collieries require a convenient, economical, and reliable supply of power. The following classification will be found useful in dividing up the subject into groups:—(1) Collieries with uneconomical steam-plant, (2) Collieries with steam-plant running fairly economically. (3) Collieries equipped with coke-oven plant, where a large supply of waste-gas is available, and (4) new collieries.

It is only possible here to consider groups (1), (2) and (3), but there

* Abstract of a Paper read before the South Staffordshire and Warwickshire Institute of Mining Engineers. Abstracted by permission of the Council of the Institution of Mining Engineers from the "Transactions," Vol. XLI., p. 24.

Digitized by Google

is one point in connection with new collieries which must not be passed over. A clear line of demarcation should be drawn between new collieries to be run in conjunction with existing pits and those which are independent. In the first case, it will probably be found that a combined plant offers the best solution, the existing steam-plant being modernised at the existing pits, and the excess power transmitted electrically to the new pit.

When collieries are working with uneconomical steam-plant, there are two questions to be considered, the first involving the scrapping of the whole plant. This is seldom possible, and circumstances, financial or otherwise, will in general prevent a wholesale scrapping policy, although there are certain cases where this would doubtless be the most far-sighted plan. The second alternative is to make the best possible use of existing plant. It is assumed that no modification of the plant is possible, and that it is too valuable to be scrapped. All the steam used will be available for driving a low-pressure turbine, and, the amount of steam being considerable, a large amount of power will be obtained. This plan has the obvious objection that the main engines become practically exhaust steam producers, and the "superior person" condemns the arrangement outright by comparing these engines to steam-pipes, which only incidentally produce a small amount of power! This is an extreme view, for there are many cases where a large saving results at a comparatively small capital cost. On the other hand, there are very few winding-engines which cannot be converted into economical machines by the addition of expansion gear. This seems a most obvious improvement, and it is only necessary to refer to an entropy diagram to see the difference in actual work produced under the two conditions. It is a noteworthy fact that there are thousands of engines in this country running without this comparatively inexpensive addition, and in most cases these engines use 100 per cent. more steam than is necessary.

There are many types of gear which can be added to existing engines, and one of the simplest is the Melling automatic cut-off gear, as fitted to the winding-engines at Littleton Colliery. With this gear there is no interference with the full steam-supply at the beginning and end of the wind. The centrifugal governor acts directly on the expansion-valves, and the action is dependent on a continuous increase of speed, which gradually alters the point of cut-off so as to reduce the steam admission. When the steam is shut off towards the end of the wind, the governor closes and the expansion-valve is practically put out of action, leaving full steam available for decking, &c., through the main steam-valves only.

Another method which has been tried for improving the economy of winders is the addition of condensing plant. This method is at best unsatisfactory, and colliery engineers are practically unanimous in opposing the use of condensing plant for this purpose. A winding-engine must be absolutely under control, and every additional item of plant introduces a further element of risk. The reduction in steam-consumption also will not exceed 10 per cent. in actual practice, although theoretically it ought to be from 15 to 20 per cent. This is due chiefly to the very irregular rate at which the steam is delivered to the condenser. The most obvious improvement on this method is to interpose an accumulator and a low-pressure turbine between the engines and the condensing plant. The condenser will be very much smaller, as the steam will now be passed through the turbine continuously, and it will work at its highest efficiency. The winding-engines, having been altered to give a fair economy, are practically in the same condition as the second group, and these can be considered together. The steam is being exhausted to the atmosphere, and is still capable of performing work in a low-pressure turbine. This amount of work is worth obtaining, although probably it will be only one-half of the amount obtainable in the first group of collieries.

Littleton may be taken as an example where a moderate estimate shows that an output of 300 kw. can be obtained from the steam exhausted by the two winders and the fan engine. This would cause no alteration in the conditions under which these engines are now running. As this figure is based on a very safe estimate, the actual output would very probably be 350 kw., or even more, and this output would assist very materially the power-supply which is normally required. Additional boilers would not be required, for the existing boilers would give considerably more than 300 kw. when the steam was supplied direct to the turbine when the winders were not running. Had the winders been running without expansion-gear, the power obtainable from the exhaust-steam would have been from 600 to 750 kw.; but this means that the winding-engines would not have been working under the best possible conditions.

If the high-pressure steam is required for long periods, it may be advisable to instal a mixed-pressure turbine which will utilise equally economically either high-pressure or low-pressure steam. The following is a typical case which is now under consideration: The colliery is of average size, with two winders and a large fan-engine. For haulages, screens, &c., which are all steam driven, about 15,000 lb. of steam per hour are required. The winders and fan take 30,000 lb., which will give 750 kw. in a low-pressure turbine. Electric driving for all the auxiliary plant will not take more than 500 kw., so that there is a clear gain of 250 kw. for coal-cutting and other work, in addition to a reduction of at least 15,000 lb. of steam per hour. This last item alone gives a saving of £300 per annum for 300 days of only 8 hours each, taking the cost of coal at 2s. 6d. per ton. Owing to special causes which cannot be discussed here, many collieries are unable to apply electric power, and it is necessary to fall back upon compressed air as the transmitting medium. Now in these cases a large proportion of the supply can be obtained by means of a turbo-compressor, driven by exhaust-steam collected from existing engines. If this steam is neglected, these engines continue to run as at present, while additional boiler-plant must be installed to supply steam for new high-pressure steam-driven compressors.

As regards collieries equipped with coke-oven plant, a different problem has to be solved. In general, it will be found that all the power required can be obtained from the steam exhausted by the existing engines, supplemented by steam from boilers fired with the coke-oven gas. Where a large supply of waste gas is available, and only a limited amount of power can be utilised, it is obviously better to instal steam plant of comparatively low efficiency. The gas-engines will have a much higher thermal efficiency, but the capital cost and upkeep will also be high, and will go far to counterbalance the efficiency. Attendance and other charges will all be in favour of the steam plant. On the other hand, where a large demand for power exists either for outside consumers or for other pits, a large gas plant driven by coke-oven gas presents many advantages; and it is only necessary to refer to the large plant of this type now running in South Wales. The total power of this plant is about 6,000 kw., but the problem is very different, owing to the continuous running and the good load-factor, both of which conditions are absent in the average colliery plant.

It will be appropriate here to consider the relation of the different parts of the plant. In the case of steam plant, the winder, the fan, and the power turbine are all in direct connection with the steam-producer, the turbine being also designed to take steam from the winder when this engine is working. In the case of gas plant, while the auxiliary plant is in the same relation to the gas-producer, the winder and the fan have also been moved down to the same position, and, if a balancer-motor is required for the winder, it is moved down one stage farther. Instead, therefore, of being in direct connection with the producer, the winder has two, and possibly three, additional links with the power-producer, both of which introduce additional risks.

The chief argument against a gas plant for collieries is that it makes electrical winding practically compulsory. It has not yet been suggested that winders should be driven direct by gas-engines, and if a steam-driven winder, with gas for the supplementary plant, be adopted, the complication of two systems is introduced, of neither of which is taken complete advantage. Electric winding is now on its trial, and it is only necessary to refer members to the recent discussion at Newcastle-upon-Tyne.* Mr. Mountain has demonstrated the excessive expenditure both in capital and on running charges of the complete electrical plant as against steam winding, the exhaust being utilised in turbines. These remarks are not intended to imply a general objection to electrical winding. The writer has in mind at least two cases—one in South Wales and the other in Yorkshire—where new pits are being entirely driven by electricity. The power is being transmitted from older pits, in which the surface plant and winders are steam driven. In addition to the supply of a large amount of electric power on the spot, there is a large surplus which will be used at the new pits. At one of these there will not be a single boiler. This appears to the writer a most convincing argument in favour of using exhaust steam wherever it is available.

It is obvious also that very few collieries are prepared to scrap existing plant, and, if they decide to do so, it is necessary to compare modern steam winders with modern gas plant and electric winders and the simplicity of operation of the steam winder will in most cases be the deciding factor. Old steam winders are notoriously uneconomical, but many of these could have their useful life extended, and their steam consumption reduced to a reasonable figure, by the addition of an inexpensive automatic cut-off and expansion gear.

In conclusion, the writer thinks it necessary to add a word of warning. He has discussed the subject with many colliery men, and their unanimous opinion demands simplicity—not only simple plant requiring comparatively little in the way of repairs, but,

* *See* "Trans." Inst.M.E., 1910, Vol. XL., p. 307.

Digitized by Google

above all, simplicity of operation. The writer contends, therefore, that the maximum of simplicity with economy is obtained in the average colliery by improving the steam conditions of the winders, and utilising their exhaust to drive a low-pressure turbine. These plants are absolutely independent of each other. The winders are under the absolute control of the drivers, and are run under exactly the same conditions whether the turbine is running or not. The power supplied by the turbo-plant, whether the transmission medium be electricity or compressed air, will drive all the underground plant in addition to the outlying plant on the surface; and, finally, the turbines use all the low-pressure steam available to its utmost advantage, and automatically use only sufficient extra high-pressure steam required to make up the exact output.

DISCUSSION.

Mr. A. McKINSTRY (Trafford Park, Manchester) said he was disappointed that Mr. Burns had not gone into the question of the cost of power as produced by the plant which he had described. After all, assuming that the different plants were equally reliable and equally simple, the average colliery owner and colliery engineer would want to know what the power would cost. He agreed with Mr. Burns that each case must be treated on its merits in deciding which plant would be most suitable, and he would not take up the attitude that gas-plants were the most suitable in every case for colliery work; but he was prepared to offer some justification for the installation of the gas plant at Littleton, because, so far as he had been able to obtain figures, the plant was producing power as economically as it was guaranteed to do, and under such conditions certainly justified its introduction from the point of view of power-production cost. With regard to simplicity, in the gas-producer itself there was no moving part, except a steam blower. Coming to the engines themselves, members could form their own conclusions as to their simplicity. The auxiliary gear—namely, the small battery and charging outfit for the ignition and the motor-driven compressor with air-tanks for providing compressed air for starting—was much simpler than the auxiliary apparatus connected with an exhaust steam installation. Mr. Burns had suggested that it might have been possible at Littleton to put down exhaust-steam turbines, and so utilise the powers of the exhaust steam from the various steam-engines. He (Mr. McKinstry) was personally not in a position to speak with regard to the amount of steam-plant in detail that was at Littleton, but no doubt the amount of exhaust steam available, the facility for collecting this at one central point, the question of condensing water, the cost of proper steam accumulators, and the capital cost were all taken into consideration by the Littleton authorities before issuing the specifications calling for a gas plant.

Mr. J. BRINDLEY (Wolverhampton) said that the gas plant at Littleton impressed him as being an uneconomical plant. He was sorry that none of the gentlemen who had spoken that day had given them any figures. They had no definite facts, for instance, with regard to fuel consumption, which, of course, was the main point. He did not doubt for one moment the reliability of the plant, but he did not think that it was an economical plant, and the only remark in its favour which he had heard that day was that it had been put in where there was no great amount of water available for condensing purposes.

Mr. JOHN BURNS (Rugby) replied that he was afraid it was almost impossible at short notice to give the figures that had been asked for. It was almost impossible to obtain figures with regard to working costs. The matter of capital cost was another question. At present the average market value for plant of all kinds was remarkably low. Therefore, he thought that figures based on present data would also be rather misleading. That was a point worthy of remembrance in considering the capital cost of installations.

PARLIAMENTARY INTELLIGENCE.

GLASGOW CORPORATION TELEPHONE STAFF.

In the House of Commons on Thursday last week Mr. SCOTT asked the Postmaster-General whether he would consider the desirability of extending to ex-members of the Glasgow Corporation local telephone staff now in his employ concessions with regard to the reckoning of service with the Corporation for purposes of annual leave, sick pay, pension, gratuity and superannuation similar to the concessions proposed to be granted to ex-employés of the National Telephone Co. in connection with the Telephone Transfer Bill.

Mr. SAMUEL said the telephone staff of Glasgow Corporation had been in a better position than the staff of the National Company, seeing that after a comparatively short period of employment under the Corporation on telephone duties they were taken into the service of the State more than five years before the transfer of the company's staff. He did not consider they had any claim to participate in the special arrangements made for the company's staff.

Mr. WATT also asked the Postmaster-General whether on the transfer of the Glasgow Corporation telephones to the Post Office, an assurance was given to the staff that their conditions of employment would not be less favourable than those employed under the Corporation.

Mr. H. SAMUEL said that the assurance was given, and there was no intention of departing from it. The great majority of the officers in question had received established appointments, and the increments of their class were being paid as they accrued. Two of the three officers whose cases were then under consideration had since been classed as unestablished with a scale of pay and conditions of employment which, taken altogether, were not less favourable than those they enjoyed under the Corporation. The case of the third who refused an established appointment was still engaging his attention.

TRAMCAR SPEED INDICATORS.

In the House of Commons last week Mr. WATT asked the President of the Board of Trade whether the regulation which required a speed indicator to be fitted on every car had ever been put in force by his Department; and, if not, would he say how he could ensure that the maximum speed of 16 miles per hour allowed the tramcars in Glasgow was not often exceeded, especially as the Corporation encouraged motor cars in their streets at 20 miles an hour.

Mr. BUXTON said the regulation required that a speed-indicating apparatus should be fitted to the cars if and when required by the Board of Trade. The Glasgow Corporation had not been required to fit such an appliance owing to the difficulty of procuring a reliable apparatus and the cost thereof, but he understood that improvements in speed indicators have been made, and the Board had recently suggested to tramway authorities that indicators should be fitted to a certain number of their cars for educating motormen in estimating speeds. The responsibility for seeing that the speed limits in Glasgow were observed by the motormen rested with the Corporation, and no complaints had been received by the Board that those limits were exceeded.

TEMPORARY BORROWING BY MUNICIPALITIES.

The Municipal Corporations (Temporary Borrowing) Bill, which has been introduced into the House of Commons by Mr. Harmood-Banner, is promoted by the Association of Municipal Corporations, and seeks to enable corporations to make temporary borrowings from their bankers or other persons pending the receipt of rates and other income.

Electricity in Mines.—In the House of Commons on Wednesday, Mr. SUTTON asked the Home Secretary whether, in view of the statement of the Committee on the use of electricity in mines that almost every electrical accident was preventible, and in view of the badly constructed or badly maintained apparatus in the mines, he would consider the appointment of an adequate number of competent electrical inspectors.

In reply, Mr. Churchill said he was aware of the statement by the Home Office Committee referred to in the question. The responsibility for the provision of electrical apparatus of proper type and its maintenance in a safe condition rested primarily with the management of the mine, and the new rules which the Committee had recommended, and which he was taking steps to bring into force, proposed further and more stringent requirements to ensure safety of construction and maintenance in the case of the electrical plant used in mines. It would be the duty of the inspectors to see that those requirements were carried out, and adequate provision had already been made for the purpose. An electrical inspector of mines was appointed in 1908, whose whole time was given to that work. Many of the other inspectors had the necessary electrical knowledge, and the possession of such knowledge had for some years been a condition of the appointment of all new inspectors, and, as he had already informed the House, a large increase of the inspectorate had recently been sanctioned.

Telephone Rating.—In the House of Commons last week Sir C. Kinloch-Cooke asked the Postmaster-General whether, since the Telephone Transfer Bill contained no provisions as to rating of the telephone undertaking after it has been transferred to the Government, it was the intention of the Government to make a contribution in lieu of rates to the local authorities upon the part of the undertaking other than buildings occupied by the Crown; and whether provision would be made in the bill to obviate, in the case of telephones, the effect of sec. 22 of the Telegraph Act, 1868, which had prevented the telegraph undertaking being re-assessed since the passing of that Act.

In reply, Mr. Samuel said the question was under consideration. No legislative powers were necessary in any case. The section of the Telegraph Act, 1868, quoted had no application in the present instance.

Coal Mines Bill.—The Committee stage of this bill was concluded on Wednesday.

LEGAL INTELLIGENCE.

Damage Caused by Animals on Tramcars.

At Westminster County Court on Friday last Judge Woodfall delivered judgment in an action by a Mrs. Wright against the London United Tramways (Ltd.) for £3. 19s. 6d., the value of a dress said to have been ruined through a dog tearing it when she was travelling on one of defendant company's cars, and said the question was whether a tramway company was entitled to carry dogs on their cars without taking the risk of such injuries as might be caused to passengers through the behaviour of the dogs. The duty of carriers of passengers was to use all reasonable care, skill and diligence in and about their conveyance. This duty was not limited to providing a vehicle safe and proper for the journey, but involved an obligation to use reasonable care to prevent the intrusion on the vehicle of persons, animals and things who or which might be a cause of danger or damage to passengers. In that case the tramway company, through their conductor, knowingly permitted a dog to be at large on the car. The animal caused damage to plaintiff, and he was of opinion that the company was liable for the breach of their duty to her as their passenger, and that the company's bye-laws supported that conclusion. There must be judgment for plaintiff for the amount claimed, with cost.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Aberdeen.—At the Corporation meeting on Monday Mr. Young, convener of the Tramways Committee, submitted the tramway accounts for the past year.

The total revenue was £73,470, an increase over the previous year of £2,348, and a record. The outstanding feature of the year's work was that the income per car-mile had increased from 10·77d. to 10·89d., notwithstanding that they had run 34,000 car-miles extra, and that the working expenses had been reduced from 6·13d. to 5·88d. per car-mile. The accounts were adopted.

Aldershot.—The Council have obtained sanction to a loan of £2,500 for additional generating plant.

Barking.—In a recent report on the electricity undertaking the consulting engineers (Messrs. Robt. Hammond & Son) stated that they were satisfied that an extension of the generating works was essential.

Messrs. Hammond & Son also stated that they had carefully considered Mr. H. Howard's scheme for the extension of the works, and agreed with his proposal to instal a 400 kw. Diesel engine and generator. They were of opinion that the purchase of the auxiliary plant proposed by Mr. Howard was an integral part of the scheme, and that its omission would prejudicially affect the financial results of the extensions. The cost of buildings could be reduced by a modification of the design. They had also come to the conclusion that the installation of Diesel plant would have a favourable effect upon the financial results of the undertaking.

Further consideration of the matter is postponed to enable the clerk to communicate with the firms mentioned in the report.

Barrow-in-Furness.—The tramway extension to Biggar Bank, Walney Island, was opened for traffic on Friday.

Bispham.—The Council have been authorised to borrow £10,800 for carrying out their electricity supply scheme.

Briton Ferry.—The Council have applied for sanction to a loan of £1,200 for extensions of the electricity works.

Burnley.—The Council have received sanction to a loan of £8,552 for extensions of the generating plant, but £471 was deducted for superseded plant.

The Board of Trade recently recommended the trial of speed indicators on the tramcars. The tramways manager (Mr. H. Mozley) has reported on the matter, and the Tramways Committee have informed the Board that when a speed indicator is made satisfactory for bogie cars the Corporation will consider the advisability of adopting it.

Calorific Tests of Fuel.—We have received a letter from Mr. John B. C. Kershaw, in which he calls attention to the unsatisfactory nature of Berthier's test (referred to at the recent Convention of the Incorporated Municipal Electrical Association). In regard to this test, Poole in his book on "The Calorific Power of Fuels," states that The formula is faulty, as was shown by some of Berthier's own determinations in which contradictory results were obtained. Dr. Ure showed that no uniform results could be obtained using the same materials. Scheurer-Kestner in 1892 showed that the formula not only gave erroneous results, but actually reversed the relation of the combustibles. In one case cited the heats actually obtained by a calorimeter were 8,813 and 8,750, while by the litharge test they were 7,547 and 7,977. The results were not only low, but reversed the ratio.

Customs Duties.—According to recent decisions, the import duty on illumination devices (gas or electric) imported into British South Africa is 3 per cent., and on Stolz electrophones 15 per cent. ad val., the rebate on British goods being 3 per cent. in both cases.

Dublin.—The L.G. Board have now sanctioned the borrowing of £100,000 (including £50,000 already sanctioned) for the electricity supply department, but the Board are of opinion that it is desirable before sanction to borrowing beyond that amount is given, a clear statement of expenditure and definite proposals, supported by plans, specifications and estimates, for any further works should be submitted. The Corporation had applied for authority to borrow £158,817.

Egham.—The Board of Trade have granted the application of the Egham & District Electric Light Co. for the erection of a generating station at Egham Causeway.

Electric Pumping.—At the meeting of J. Grayson Lowood & Co. last week the chairman (Mr. C. B. Stuart-Wortley, M.P.) said they had made considerable headway towards a better state of working conditions in the Deepcar mine, a change having been made in the pumping plant from steam to electricity. The new electric pumping plant was got to work a few days before Christmas, and had rendered excellent service since. Therefore, they confidently believed that the difficulty caused by inrushes of water into the mine had been surmounted at least for many years to come, without any further likelihood of heavy expenditure, except that they purposed duplicating the motive power at an opportune time. The working conditions in the mine would be improved by the change, and the directors anticipated a considerable saving in the cost of pumping.

Epsom.—Last week the Council considered a report by the resident electrical engineer (Mr. A. E. Gilling) on the advantages of installing a Diesel engine at the electricity works.

Mr. GILLING stated that with the Diesel engine there were no stand-by losses, whilst it was considerably more efficient at light loads. The engine consumed the cheapest class of liquid fuel—viz., petroleum residue—the average cost of which was about 2d. per gallon. By installing a Diesel engine they would have extra plant to cope with increased demands in future. The Diesel set, being a self-contained producer of power, would be entirely independent of the present plant, and would give further valuable safeguards against interruptions of supply, and the total cost of production would be reduced. The present steam costs for generating 250,000 units were £888. 19s. 2d.; similar cost by Diesel engine would be £245. 4s. 2d., showing a saving of £643. 15s. The attendance required for a Diesel engine was considerably less than that required for a steam plant, and although perhaps they might make some saving under that heading, it was not advisable seriously to diminish the present small staff. The capital costs were estimated at £3,500, including £3,100 for the Diesel engine and generator. The result would be reduction in works costs £639. 15s., less extra capital charges (interest and repayment of capital) £350, net saving £289. 15s.

The Electricity Committee recommended that an electrical expert be appointed to advise on Mr. Gilling's scheme at a fee not to exceed £5. The Committee also complimented Mr. Gilling on the financial and technical success of the undertaking since his appointment as resident engineer, and recommended that the annual increment of £10 (fixed on July 1, 1909) be increased to £20 as from Aug. 15, 1911, until the maximum of £250 was reached.

Consideration of the Extension Scheme was adjourned till after the holidays.

Finchley (Middlesex).—The Council have retained counsel to represent them in their appeal against the increase in the assessment of their electricity works from £400 to £1,800.

Grimsby.—The borough electrical engineer (Mr. W. A. Vignoles) is preparing a specification for the electric lighting of the new lending library, and he is also preparing to report upon a proposal to reduce the charge for electricity to private consumers from 3½d. to 3d. per unit.

Hastings.—The Council have decided not to entertain the petition, signed by 4,225 residents, in favour of the substitution of overhead for surface contact system of traction on the front.

Hereford.—Application has been made for sanction to a loan of £2,350 for the electricity department, including £500 for mains, £1,000 for services and £850 for mechanical stokers.

Hornsey.—Sanction has been received by the Council to a loan of £9,000 for electricity supply extensions.

Ilkley.—The Council have refused to entertain the scheme of the Wharfedale Electric Lighting Co. for supplying electricity to the Council in bulk.

Islington (London).—At the meeting of the Council on Friday the Lighting Committee reported that they had had under consideration the price paid by the Council for electricity supplied for public lighting, and they recommended that the same should be reduced from £12,100 to £11,000, and also that £1,000 out of the surplus funds of the undertaking should be applied to relief of rates.

Leeds.—On Wednesday evening last week the tramway employés resolved to go out on strike, but on Friday morning they resumed work in accordance with their acceptance of the Tramway Committee's terms.

The strike was thus confined to a single day. The men's hours have been reduced from 60 to 54 a week, whilst there has been a compromise over the "spread-over" terms, and a revised set of conditions with regard to waiting for cars has been agreed upon.

Light Railways.—The Board of Trade has modified and confirmed the light railway order for the construction of a light railway at Weston-super-Mare, connecting the Weston, Clevedon and Portishead light railway with the tramways of the Weston-super-Mare & District Electric Supply Co.

Digitized by Google

Llandudno.—The charge for electric current for private lighting has been reduced ½d. a unit.

L.C.C. Tramways.—Islington Council have agreed to contribute £20,000 towards the cost of widening Balls Pond-road to enable a double line of electric tramways to be constructed.

Mill Driving.—The directors of the Victoria Mill, Rishton, have decided to adopt electric driving. It is stated that this is the first mill in the district to be operated electrically. There will be a separate motor for each loom.

Nelson.—The Board of Trade have authorised the supply of electricity in bulk to Brierfield, but not in connection with tramways worked by Burnley Corporation.

Newport (Mon.).—A long discussion took place at Tuesday's Council meeting on the position of the tramways and electricity supply undertakings.

Councillor Moxon said they had gone to the expense of employing an expert (Mr. C. P. Sparks) to report on the undertaking, and they had practically discarded his recommendations. They were charging the tramways department 1·35d. per unit, while they charged private concerns only 1·18d. for power. Mr. Sparks had warned them that they were on dangerous ground, and that though the concern had been running 10 years they had made no provision for depreciation. The rolling stock of the tramways department was not in good condition, and an enquiry was necessary.

Ultimately it was unanimously resolved to ask the Electricity Committee to consider at an early date and report to the Council upon the whole position of the electrical undertaking.

North Berwick.—The Council have agreed to lease a piece of ground to Messrs. Crompton & Co. for electricity supply works.

Oulton Broad.—The Council have applied for sanction to the use of overhead wires for electricity supply.

Patent Notices.—Application has been made for the restoration of patents No. 13,746/1903, granted to S. M. Young for "Improved method for operating signals on electric railways," and No. 7,320/1907, granted to the Saltpetersäure Industrie Gesellschaft G.m.b.H.) for "Improvements in arc furnaces for the electrical treatment of gases." Notices of opposition must be given at the Patent Office, London, W.C. by Aug. 28.

Presentations.—Chelmsford staff of Messrs. Crompton & Co. have presented a canteen of cutlery to Mr. M. E. Sizer on his marriage.

The staff of the electrical department at Portsmouth Dockyard have presented a gold watch and travelling case to Mr. K. N. Saye, power station supervisor, on his departure for the Straits Settlements.

St. Helens.—The Council will give a supply of electrical energy to the Earlestown works of the L. & N.W. Railway Co.

The L. & N.W. Co. guarantee a minimum consumption equal to 500 kw. for 21 years, with the option for the company to discontinue supply at the end of 14 years on paying the Corporation compensation in respect of the mains laid on the company's property. Two new high-tension feeders are to be laid from the power station to St. Helens Junction and thence along the permanent way of the railway company to Earlestown. The new feeders will be available for a supply to the Parr side of Newton-le-Willows and also to the works of Messrs. Bolton & Sons.

Sheffield.—On Wednesday the Electric Light Committee reported that they desired to increase their expenditure on capital account during the current year by £11,503, the balance of the loan of £78,207, raised in March, 1910, and also that they were asking for sanction to a further loan of £61,099 in connection with the extension of the Neepsend generating station.

The Tramways Committee recommended that powers be sought in the Parliamentary Bill for railless cars to be worked from the present Green terminus to Fulwood Church, and also for the subsequent construction of ordinary tramways if and when considered advisable by the Committee.

Tottenham.—Last week the Council adopted certain recommendations of the Tramways Committee which will permit of the early construction of the connecting link between the Tottenham and Edmonton tramways, giving access to Epping Forest by tramcar from Bruce Grove to Lansbury Park. The Metropolitan Electric Tramways (Ltd.) have to construct the line (about two miles) completed within 12 months.

Wimbledon.—The Borough Electrical Engineer has been instructed to lay supply mains in seven roads in Merton, and he has also been instructed to proceed with laying mains and other works necessary for giving a supply of electricity in the Malden and Coombe area as soon as the powers conferred by the Wimbledon Electric Lighting (Extension) Order, which is now awaiting confirmed by Act of Parliament. A loan to cover the cost of the work has been sanctioned.

Wireless Telegraph Notes.—22,108 messages were transmitted by the wireless station at San Catalda during 1910, an average of 60 messages per day. Two new masts have been constructed.

According to the "Marconigraph," in the course of the 12 months ending March last, 3,955 wireless weather reports were sent from ships at sea. Only 3.4 per cent. of these messages reached the Meteorological Office in time to be included in the same day's map of the Daily Weather Report. 39 per cent. were received in time to be included in the "yesterday" map published with the daily report.

The cadet ship "Mersey," belonging to the White Star Line, recently arrived in the Thames after a voyage around the world. This is said to be the first sailing ship to be equipped with wireless apparatus, which worked for 11 months without a single breakdown, and this notwithstanding that there were no operators with practical experience on board. The tribute of efficiency is due to the Marconi system and the apparatus connected therewith.

The latest adaptation of wireless is described in the Paris "Figaro," which famous journal states that Hertzian waves are being used at Epernay "for shaking up the sediment in champagne after it has been bottled." To what base uses are we come.

Following the example of Norway, Russia is establishing wireless telegraph stations in the Extreme North. It has been decided to erect four stations, one at Petschora, another at Vaigatz, one on the Murman coast and one on White Island, the estimated cost of this work being between £30,000 and £40,000.

A consular report states that the Uruguayan Government are installing a service of wireless telegraphy in the country on the Telefunken system.

Three land stations are to be erected, one at Cerrito, a point near Montevideo (range 500 miles); the second at Paso de los Toros, about the centre of the Republic, 156 miles north of the capital (range 312 miles); and the third at Rivera, on the Brazilian frontier, 175 miles northwards from Paso de los Toros (range 312 miles). Of these the first only will be for public use, the others being reserved for military purposes. The Uruguay army is to be furnished with portable instruments, five of 125 miles range and four of 25 miles. Five vessels of the fleet will be provided with apparatus ranging from 250 miles to 62 miles. Installations are to be placed on Lobos Island and on the lightship on the "English Bank," the latter with a range of 50 miles. The Lobos Island installation will be employed for the transmission of signals made by sailing ships and others that pass outside the island and so are unable to signal by means of flags to the Government telegraphic station at the extremity of Punta del Este, and the installation on the "English Bank" will be of value in case of shipwreck at that point. The apparatus is, it is said, on order from Berlin.

Wolverhampton.—Last week the Council adopted a recommendation to purchase, at a cost of £1,500, a 400 kw. rotary converter and switchgear for giving a supply of energy to the Knowles Oxygen Co.

Wrexham.—The L.G. Board, who held an inquiry on June 2 into the Council's application for sanction to a loan for electricity supply, have now granted sanctions for the following works:—

Excess expenditure on previous loans, £437 (for 20 years); traction battery, £450 (7 years); meters, £140 (4 years); extensions to feed pumps, forced draught furnace, automatic expansion gear to one engine, £450 (10 years); street lighting, £500 (10 years). A period of 15 years has been allowed in the following cases: Extension to condensers, £80; electrical instruments and sundries, £50; machinery tools, £220; erecting and fitting out stores and offices, £350; coal elevator, £300; switchboard, £260; reversible booster, £150; switchboard, £100; cabling, £50, and concrete flooring, £50.

At the inquiry strong opposition was made by the local gas company, but this has had no influence with the L.G. Board, since the Council have secured practically everything they asked for. Included in the original application was £600 for a switchboard, but as £340 remained to be paid off on the old switchboard, this was deducted from the £600. An item of £114 for excess expenditure up to March 31, 1908, which was not submitted to the Board at the last inquiry, the Board has declined to sanction and this will have to be made good out of revenue. In addition to the over-expenditure on previous loans, certain work has already been carried out, as follows: Extension of feed pumps, forced draught apparatus, fitting out stores and offices, extension to condensers, electrical instruments and sundries and meters.

COLONIAL AND FOREIGN NOTES.

Argentina.—The "Review of the River Plate" states that at Carmen de Areco there is a proposal to form a local company for erecting electricity works.

Cordoba Government recently invited tenders for the purchase of their electricity station in Cordoba City, which has never been in operation. The upset price was $150,000 (paper).

Patagones Municipality received only one tender (from D. A. Sorondo) for the equipment of electricity works, and a concession for 15 years is to be granted to him.

Mr. J. J. Costa has applied to Congress for a concession for an electric tramway from Ingeniero White to Puerto Galvan and the city of Bahia Blanca.

The Argentine Post Office Department have laid a new submarine cable 34 miles in length between Buenos Ayres (Argentina) and Martin Garcia (Uruguay).

The Government has authorised the United River Plate Telephone Co. to renew its lines to La Plata. The company intend to lay underground lines in La Plata, and to substitute the C.B. for the magneto system.

Australasia.—The "Australian Mining Standard" states that Port Melbourne Council recently appointed a committee to

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included

consider the best means of supplying electrical energy in the district.

Messrs. F. A. McCarty & Co. have presented their report to Shepparton (Victoria) Council on alternative schemes for electric lighting and improved water supply. The system of supply proposed in each case is three-wire d.c., with a pressure of 460 volts for power and 230 for lighting. The first scheme includes suction gas engines, the second locomobile pattern steam engines, and the third Diesel oil engines, the total capital cost being £7.974, £8.444 and £7.894 respectively. It is estimated that the total maximum demand in the first year would be 210 H.P. and the average 120 H.P.

Kilmore (Victoria) Council recently put in an auxiliary engine, and invited tenders for the supply of a battery of accumulators.

Daylesford (Victoria) Council have decided to borrow £4.000 for erection and equipment of electricity works.

The Railways Standing Committee of the Victorian Government have reported on the proposal to duplicate and regrade certain suburban railway lines. The report favours the adoption of electric traction, and recommends that the level crossings on the Caulfield and Camberwell lines be abolished, at a cost of £157.000 and £153.000, part of which should be contributed by the local authorities. The amount which would have to be spent on duplicating the Caulfield and Camberwell lines if steam traction were continued would go a long way towards paying for their electrification. Electricity (says the report) would give a cleaner, faster, more frequent and safer service, and would remove the risk of narrow platforms becoming congested.

In giving evidence (at Sydney) before the Victorian Traffic Commission recently the Lord Mayor of Sydney (Ald. Taylor) said the profits of tramways ought to be used for the development of a certain prescribed radius. He would abolish all overhead wires.—The town clerk (Mr. Nesbitt) favoured the establishment of a central authority similar to London County Council, to control tramways, lighting, &c.—Mr. T. R. Johnson, Commissioner of N.S.W. Railways and Tramways, thought Victoria might defer action with regard to electrification.—Mr. W. Fitzpatrick, chairman of the Railway Commissioners, said the Commissioners did not consider the circumstances justified them in recommending the electrification of the suburban lines at present. The more extended experience of other countries in which electric traction was receiving attention would be valuable to them.

On June 7 the Premier of South Australia (Mr. J. G. Verran) formally opened the new power station of the Adelaide Municipal Tramway Trust. The Trust has 75 miles of single track and 163 cars. Work is now in hand in connection with the outer circle, comprising lines to Prospect, Nailsworth, Enfield, Glen Osmond, Mitcham, Paradise, Magill and Goodwood. The substitution of electric for horse traction had (said the Premier) proved satisfactory.

The Railway Commissioner has informed Newcastle (N.S.W.) Council that he could not supply current for the Newcastle tramways in the event of their electrification.

A company has been formed at Murchison (Victoria) to run a co-operative butter factory and electric light and power plant for public and private supply. The local waterworks trust will take energy from the new company for pumping.

Tungamah (Victoria) Shire Council are considering a proposal to light the town electrically.

It is stated that Mr. F. W. Paul has been appointed as a Royal Commissioner to report as to the suitability of Australian ores for the manufacture of iron and steel, the cost of plant capable of producing the iron and steel likely to be required in future by the State Governments and the Commonwealth, including rails, bridges, &c., plates for shipbuilding, &c.

Alexandria (N.S.W.) Council have entered into a 10-years' agreement to take a supply of current from Sydney Council, and notice has been given for the gas lighting to be stopped on Jan. 1 next. In addition to the public lighting demand, there are over 100 factories in Alexandria, most of which require electric power.

Brazil.—The Government has approved the plans for urgent harbour works at Manaos (including electric hoists) at a cost of £59.000.

Canada.—It is stated that the Government of Alberta are constructing 800 miles of new telephone line this year. There are 4.000 miles of trunk and 3.000 miles of rural lines, and over 11.000 subscribers.

Chili.—The plans submitted by Messrs. C. C. Larrain and J. Gross for electricity supply works and electric tramways in the communal district of Barrancas, and by Senor D. R. S. Ruiz for an electric tramway in Viña del Mar, have been approved by the Minister of the Interior.

China.—A consular report states that net imports at Shanghai in 1910 included electrical materials value £62.287 compared with £66.656 and £63.482 in 1909 and 1908 respectively, and machinery £163.297 (compared with £49.350 and £169.674), railway materials £97.239 (compared with £70.474 and £152.458).

In a Consular report on the trade of China during 1910 it is stated that the Chinese telegraphs (under a purely native administration) are one of the most costly and at the same time one of the worst managed telegraph systems in the world.

The value of the imports of electrical materials and fittings in 1910 was £186.775, against £177.676 in 1909 and £23,257 in 1908, and the values of telegraph materials were £63.666, £45.199 and £47.611 respectively.

It is stated that railways are being constructed and projected in every province; coal and other mines are being opened, and factories are springing up in all directions. British manufacturers are urged to take steps to maintain their dominant position in the Chinese machinery market.

India.—"Indian Engineering" says the Public Works Minister of the Jammu and Kashmir State announces that 400 kw. of electric power is for disposal at the Mohora generating station or along the transmission line to Baramulla and Srinagar, at £8 per horse-power per annum for 24 hours' daily service.

Italy.—Rome municipality have granted to M. Berthelot (manager of the Cie du Chemin de Fer Metropolitan of Paris) and M. G. Boucher (Provincial Councillor of the Seine Department) a concession for the construction of an electric railway (partly underground) from the centre of Rome to Ostia, on the coast, a distance of about 18 miles.

A consular report states that the railway and tramcar construction works at Naples delivered 522 cars to the State Railway and 60 cars to the tramway company during 1910, besides repairing 922 railway cars.

A report from Bari (in the Naples consular district) states that the local electrical company, which in 1909 started the Bari-Carbonara tramway, extended the service to the town last year and it is expected that further lines to Canneto and perhaps from Cassano to Murge will be added shortly. Electric tramways from Trani to Andria and to Corato are also to be laid.

The British Consul at Rome says the report of the Banca Commerciale Italiana states that the metal factories have yielded very satisfactory results. The report expresses satisfaction at the general economic conditions, and the increased industrial prosperity is largely attributed to the extensive use which is being made of the power supplied by the abundant waterfalls from the Alps and the Apennines.

Rome municipality are now establishing electricity supply works. The Anglo-Roman Gas Co., which was established in 1852, has hitherto had no competitors. The tramway service in Rome has until lately been conducted by a company, but recently the city authorities have constructed and started working some new lines.

At Civita Vecchia harbour improvement works are progressing, though somewhat slowly. All the quays along the breakwaters will be equipped with electric cranes.

Melbourne (Victoria).—The annual report of the Electric Supply Committee for the year ended Feb. 28 states that gross revenue was £120.363 (against £113.579 in previous year), working expenses £56.429, gross profit £63.034.

After meeting capital charges and placing £20,766 to depreciation there was a balance of £19.532. The committee recommended a further special appropriation of £5.000 to depreciation. Revenue from sales of current for private lighting was £64.944 (against £62.758) and for power and heating £23,570 (£19.846). Units sold for private lighting were 3,803.091 (increase 149,028), and for power and heating 3,098.960 (increase 537.969). Total units sold, including public lighting, were 8,920.489 (increase 760,526), total generated 10.75 (increase 969,478).

Pemba.—Fifty miles of telephone line (14 miles constructed during 1910) now connect the principal towns in Pemba, an island near Zanzibar.

Russia.—Reval municipal authorities have applied for authority to borrow 1,500,000 roubles (about £158.000) for public works including electricity supply works.

Spain.—Spain has some natural advantages, and the past year has witnessed her slow awakening to the possibilities of one of her most important sources of wealth—her mountain streams. Madrid has taken the lead in this development. A large electric generating station, utilising the power of a waterfall some 125 miles distant, has been established, and the owning company state that they are in a position to supply for industrial purposes electrical energy at a cheaper rate per unit than in any other European centre. The establishment of other power stations, taking water power from the streams of the Guadarrama mountains, is contemplated.

The Belgian Consul at Almeira states that the Southern Railway have recently erected a power station near Santa Fé, on the left bank of the Andarax river, for supplying electrical energy for traction on a section of line (14 miles) between Gergal and Santa Fé. The plant was supplied in France. This is stated to be the first example of electric traction on a standard Spanish railway.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Barnsley.—The capital expended at March 31 was £78,192, an increase of £751 during past year.

The revenue was £13,529, including £13,363 from sale of current by meter, and the total expenditure £6,090, leaving a gross profit of £7,439. Interest required £2,486 and sinking fund £744 and sinking fund and instalments of principal £2,890, leaving a net profit of £2,054. 1,802,164 units were generated and 1,544,192 were sold (991,573 to private consumers, 271,185 for traction and 281,434 for public lighting); there are 2[illegible] public lamps and the total maximum supply demanded was 905 kw.

Birkenhead.—The total revenue of the tramways department for the year ended March 31 was £57,662, the traffic receipts being £56,717.

The total expenditure was £36,969, and after providing legal and other expenses the balance was £21,255. Interest on capital absorbed £9,556, sinking fund £9,503, and, after paying bank interest, income tax, &c., there was a deficit of £115 (against a profit of £1,833), which was increased to £1,115 by the contribution of £1,000 to renewals fund. The capital expended is £366,128, an increase of £9. 12,640,261 passengers were carried (against 12,283,344) and 1,207,761 car-miles run (against 1,201,476). The year's results were adversely affected by an increase of £1,851 in working expenses, of £286 in capital charges and £760 in legal expenses.

Doncaster.—The revenue of the electricity department for the year ended March 31 was £11,799, including £6,780 from sale of current by meter and £4,263 from the tramways department.

The total expenses came to £6,018, leaving a gross profit of £5,781. Interest required £1,496 and sinking fund instalments £1,973, and after adding £315 to sinking fund to make good deficiency in interest, the net balance (£2,022) was carried to renewal fund. The total capital expended is £97,849, an increase of £3,349.

The total receipts of the tramways were £16,513 and the expenses [illegible],207, leaving a gross profit. Interest required £2,729 and sinking fund instalments, &c., £1,589, leaving a deficit of £81. The capital expenditure is £94,757, an increase of £3,362. The passengers carried numbered 4,131,412 and the car-miles run 503,185. 682,083 units (1·35 per car-mile) of current were consumed. The average traffic revenue was [illegible]3d., and the total expenses 7·91d. per car-mile.

Gloucester.—The accounts of the light railways department for the year ended March 31 show total income of £15,968, including £14,965 for the revenue.

The operating expenses came to £12,105, leaving a gross profit of £[illegible]64. After providing £4,271 for interest and £792 paid to County Council for rent of county portion of lines, there was an adverse balance, after taking credit for £2,925 from the city fund account, of £1,726. The sinking fund came to £1,980. The capital expended is £131,316, an increase of £15. 3,853,492 passengers were carried and 586,290 car-miles run. The operating expenses were 75 per cent. of the receipts.

Greenock.—At the meeting of the Electricity Committee on Monday last the Convener (Councillor J. W. Bailey) intimated that, although the annual accounts had not yet been fully prepared, he was able to indicate that the output for the year showed a great increase, rising from [illegible],000,000 to 7,000,000 units.

It was estimated that there would be a profit balance of £2,000, but this had been greatly exceeded. The net profit, after meeting all charges, including interest and sinking fund, amounted to fully £5,000. The allocation of the surplus would be considered next week at the meeting of the Corporation, when the annual report of the department would also be considered.

Hull.—The accounts of the electricity supply and tramways departments for the year ended May 15 have been issued:—

The income from sale of current was £23,467, and the working expenses £13,306, leaving a gross profit of £10,161. During the year £1,000 was transferred from the surplus of the electricity undertaking for relief of rates, and a reduction of charges has also been made.

The tramway undertaking began the year with a debit balance of £[illegible]. The receipts amounted to £31,517, the working expenses were £17,789, leaving a gross profit of £13,728. Capital charges were £14,769 and other expenses £862, leaving a debit balance of £1,903.

Sheffield.—The accounts of the electricity supply department were approved by the Council last week.

The total capital expended was £86,959, an increase of £1,519. The revenue from sale of current was £9,512, the income from public lamps, meter rental and sewage pumping making a total of £11,301. The total expenses were £6,680, leaving a gross profit of £4,620. 10s. 6d. was required £1,801 and redemption fund £3,115, leaving a deficit of £296, against £802. 1,190,160 units were sold (against 1,185,521), including 386,203 (386,220) for private lighting, 141,184 (147,191) for public lighting, and 662,773 (652,120) for power. There are 729 consumers, an increase of 42, and the maximum supply demanded 889 kw., an increase of 1,205. The total works cost was 1·34d. (1·37d.), and the total cost 2·33d. (2·33d.) per unit sold.

The chairman of the Electricity Committee (Councillor ENGLAND), in moving the adoption of the accounts, said their prospects were improving. The changes made in the scale of charges for power consumers had enabled them to offer reasonable terms to large and long-hour consumers, and in consequence, they were obtaining customers it was impossible previously to persuade to take current.

Watford.—1,148 consumers, with an equivalent of 67,371 32-watt lamps, are now connected to the mains.

During the past year the profit was £790, and during the first quarter of the present year there has been an increase, compared with the corresponding quarter last year, of 43 per cent. in the units sold, and of 36 per cent. in revenue, the increase in working expenses being only 3 per cent. Mr. Goodrich, chairman of the Electricity Committee, is confident that the net profit for the current year will run into four figures.

Wimbledon.—In presenting the accounts of the electricity department for the past year Councillor Stuart stated at the last meeting of the Council that the figures would compare favourably with any public company.

Councillor STUART said the cost per unit was lower than that of the preceding year, although they generated 250,000 more units. The cost of maintenance and repairs was slightly higher. The total cost was 2·7d. per unit, as against 2·922d. in the previous year, and the surplus was £2,100, against £1,986. They had increased the number of consumers at the rate of over 8 per cent., but he thought they would do a great deal better this year in view of the extensions in hand. The reserve fund amounted to over £13,000, which was not quite up to what they required, 10 per cent. of the capital, but it was very satisfactory. He thought the Committee should consider whether or not it was time to sell their Consols and invest the money in Corporation loans at 3½ per cent. He had spent considerable time on the street lighting question, and so far as he could see the charge was a very reasonable one. Some of the arc lamps were expensive, and if they substituted others for them and got a good light he thought they could save something like £500 a year. He had charged 2½ per cent. for depreciation and reserve on the capital outstanding. The profit was 7¼ per cent. on the capital, but some Councillors did not appreciate the fact that they had to pay 9 per cent. in repayment of loans and interest. He hoped they would not have any serious additions to the capital unless it was for purposes of new business. They hoped to add many consumers in Merton during the coming year, which would help them considerably, and then there was the Maldens and Coombe, where they would no doubt have a very remunerative business.

The accounts were adopted.

TRADE NOTES AND NOTICES.

TENDERS INVITED

CLEETHORPES-WITH-THRUNSCOE Urban District Council invite tenders for the supply, delivery and laying down of a system of vulcanised bitumen distribution and feeder cables on the low-pressure three-wire d.c. system. Specification, conditions of contract and form of tender from the clerk of the Council, Mr. B. Greaves, Council offices, Cleethorpes, to whom tenders must be sent by noon of Saturday, Sept. 2. Specifications and general conditions of contract may be seen at the offices of the consulting engineers, Messrs. Vesey Brown & Hall, Milburn House, Newcastle-on-Tyne. See also an advertisement.

The Municipal Commissioners of PENANG invite tenders for the supply and delivery, f.o.b. British port, of one 500 kw. steam dynamo engine or turbine with ejector condensing plant and switchgear. Specifications, general conditions and form of tender may be obtained from the consulting engineers, Messrs. Preece, Cardew & Snell, 8, Queen Anne's-gate, Westminster, S.W., to whom tenders (in duplicate) are to be sent by noon of Tuesday Sept. 5. See also an advertisement.

Tenders are invited up to Sept. 26 for the supply of telephone material and 30 miles of telephone cable to the Postmaster-General's Department in VICTORIA. Specifications, forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W., See also an advertisement.

Tenders are invited for the supply of a desiccating plant, to the Postmaster-General's department in NEW SOUTH WALES. Forms o tender, specifications, &c., may be obtained from the Commonwealth offices, 72, Victoria-street, London, S.W. See an advertisement.

Tenders will be received until noon Monday Sept. 18 for the supply of Swedish, Norwegian, Finland or Russian red fir telegraph poles, for the GENERAL POST OFFICE. Forms of tender, containing all particulars, may be obtained from the Controller of Stores, Mr. G. Morgan, Stores Department, G.P.O., 17 and 19, Bedford-street, London, W.C., See also an advertisement.

The COMMISSIONERS OF H.M. WORKS AND PUBLIC BUILDINGS are prepared to receive tenders for the supply of electrical accessories for three years from Sept. 1 next. Forms of tender and particulars from the Storekeeper, H.M. Office of Works, 12, Lambeth Palace-road, S.E. Tenders by Friday, Aug. 18, to the Secretary, H.M. Office of Works, Storey's Gate, London, S.W.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1911 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 24th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1911 Big Blue Book, making it the most complete work of the kind ever published

The Council of the County Borough of WEST HAM invite tenders for (*a*) water tube boilers, (*b*) coal handling and discharging plant, (*c*) 5,000 kw. turbo-alternator, with condensing plant, (*d*) river service pipe-work, (*e*) centrifugal pumps, (*f*) 750 kw. converter (two-phase to d.c.). Specification, form of tender, &c., from Mr. H. H. Couzens, engineer and manager, 84, Romford-road, Stratford. Tenders to the town clerk, Mr. Fred E. Hilleary, Town Hall, Stratford, E., by 10 a.m. Aug. 31.

BIRMINGHAM Corporation require tenders by noon Aug. 18 for erection of a tramway depot in Whitmore-street, Hockley, Birmingham. Particulars from Mr. A. Rowse, King's Court, Colmore-row, Birmingham.

Tenders are invited by the FARNHAM GAS & ELECTRICITY Co. for the supply and erection of two high-speed Diesel oil engines coupled to two 90 kw. alternators with direct-coupled exciters, piping, tanks, overhead traveller and accessories, and main high-tension switchboard. Tenders to the Secretary by noon Aug. 16.

LONDON COUNTY COUNCIL invite tenders for four sets of crushing rolls, screens and elevators, and two sets of sand drying plant, for the tramways department. Tenders by 11 a.m. Aug. 22.

IPSWICH Corporation want tenders by Aug. 24 for one year's supply of paper-insulated underground cables. Specification from Mr. F. Ayton, Electricity Works, Constantine-road, Ipswich.

SWINTON AND PENDLEBURY Council require tenders by 9 a.m. Aug. 22 for the electric lighting of a new school off Cromwell-road, Pendlebury. Plans, &c., from Mr. T. J. Bushell, John Dalton-street, Manchester.

Tenders are invited up to Aug. 23 for supply of letter-box fronts to the Postmaster-General's Department in QUEENSLAND and for telegraph, telephone, and electric lighting material to the Deputy Postmaster-General in NEW SOUTH WALES; and for telegraph and telephone material to the Postmaster-General's Department in SOUTH AUSTRALIA; up to Aug. 30 for supply of porcelain insulators, copper wire, sleeves, &c., to the Postmaster-General's department in SOUTH AUSTRALIA; and up to Sept. 5 for the supply of (*a*) 10,000 protectors and (*b*) sundries to the Postmaster-General's Department in VICTORIA. Tender forms and specifications at the Commonwealth Office, 72, Victoria-street, London, S.W.

The Metropolitan Water and Sewerage Board, Albert-street, BRISBANE, Queensland, want tenders by noon Jan. 30 next for supply and erection, of one, two or three complete units, each consisting of power generating plant and pump or pumps to lift not less than 6,000,000 gallons per day. Particulars from the Secretary, and forms from the Agent-General for Queensland.

The Municipal Council of BUDAPEST, Hungary, require tenders for the manufacture and supply of plant for a steam-driven electrical generating station, including two groups of three-phase turbo-generators (5,000 kw. each), 10,000 volts 50 cycles, boiler equipment for mechanical output of 5,000 kw. with reserve, pipeline, central switching and accessory equipments, travelling crane for engine room and coal-conveying plant. Specifications, &c., can be obtained at the Presidial Section of the Council, 9: IV., Városház-utca 16, II. 1, Budapest. Tenders by 11 a.m. Sept. 30.

Tenders will be received at the Town Hall, SYZRAN, Russia, on Oct. 14, for the construction of an electric tramway and the supply of electrical energy for lighting.

The time for the receipt of tenders by the Ministry of Public Works, Constantinople, for an electric power and tramway concession for JERUSALEM, is extended to Sept. 13. Specifications (in French) can be seen at 73, Basinghall-street, London, E.C.

The Public Works Department, Madrid, will receive tenders on Sept. 20 for the concession for the construction of the RENTERIA electric tramway.

The BOMBAY, BARODA & CENTRAL INDIA RAILWAY Co. want tenders by *noon* Aug. 22 for supply of steam engines and d.c. dynamos, air compressors and centrifugal pumps. Forms of tender, &c., from the Secretary, 110, Bishopsgate, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

Northallerton Council have renewed the contract with the Northallerton Electric Light & Power Co. for street lighting for five years at the following rates:—

13s. per arc lamp burning 100 hours, 3s. per 32 c.p. lamp in main street, and 3s. 9d. per 32 c.p. lamp in side streets, and 2s. 6d. per 100 hours for each 16 c.p. lamp, less 5 per cent. in each case.

Hastings Council have accepted the following tenders:—

Oliver Arc Lamp, for arc lamp carbons at 30s. per 10,000: A. H. Wood wiring Clive Vale schools, £63; Bruce & Co., wiring Tower-road technical schools, £100.

Stockport Council have accepted the following tenders:—

Walter Scott (Ltd.), tram rails, £6. 15s.. and fish plates, £9. 15s. per ton; Walker's Road & Destination Indicators (Ltd.), 36 destination indicators, £18; Morgan Crucible Co., carbon brushes; British Insulated & Helsby Cables, overhead line material.

Crook Council have accepted the tender of Pease & Partners for installing 20 25 c.p. lamps at Sunniside at £213, and supplying current at 35s. per lamp per annum.

Dundalk Council have placed an order with Sandycroft Foundry Co. for a storage battery for their electricity works.

Heston and Isleworth Council have placed an order with Kraft & Jacoby for metal filament lamps for street lighting.

Watford Council have accepted the tender of Ferranti Limited for switchgear at £175.

Shrewsbury Council have placed an order with Edwin Danks & Co. (Oldbury) for a boiler at £422. 10s.

Tunbridge Wells Council have placed an order with the West Electric Co. for a year's supply of cables.

Blackburn Council have placed an order with Joseph Wright & Co. for water softening plant.

Coventry Guardians have accepted the tender of H. J. Tew for wiring the nurses' home at £61.

Blackburn Council have placed an order with McPhail & Son for a superheater.

W. T. Henley's Telegraph Works Co. have secured the contract for all the cables required in connection with the supply of electricity to the Central India Spinning, Weaving & Mfg. Co., Nagpur.

Balmer, Lawrie & Co. have contracts for the electric lighting of camps of the Government of India, the Governor of Bombay, the Governor of the United Provinces, the Resident of Baroda and the Governor-General of Rajputana, at the Delhi Durbar.

The Madras & Southern Mahratta Railway Co. recently placed an order for two Worthington electric pumps in connection with the water supply scheme for Bangalore city station.

The Prahran-Malvern (Victoria) Tramway Trust have accepted the tender of Edgar Allen & Co. for special track work, at £1,[illegible].

Sydney (N.S.W.) Council have ordered 50 additional arc lamps, £275, and eight feeder panels (at £2. 12s. each) for sub-stations, from the Australian General Electric Co.

Mortlake (Victoria) Butter Factory have accepted the tender of Fiddes & Morgan for erection of power house, &c. (£330), and Bennie, Teare & Co. for a 60 H.P. suction gas engine (£756).

The British General Electric Co. (Sydney) recently received an order from Gisborne (N.Z.) Council for a switchboard.

Prahran-Malvern Tramways Trust have accepted the tender of British Insulated & Helsby Cables for supply and erection of overhead equipment and supply and laying of underground feeders, £4,555. 7s. 9d.

The Municipal Commissioners of Shanghai have placed an order with the General Electric Co. for Osram lamps, which include 100 c.p., 500 200 c.p. and 200 400 c.p. lamps.

Digitized by Google

Cardiff Corporation have accepted the following tenders :—

British Insulated & Helsby Cables for l.t. cable, £1,617. (Eight tenders received, from £1,680 to £1,590.)

British Insulated & Helsby Cables (lowest tender) for h.t. cable, £454. 13s. 4d. (Eight tenders received, highest £540.)

Musgrave & Co., for induced draught plant, £495. (Seven tenders received, from £710 to £460.)

E. Green & Son, for fuel economisers, £1,061. (Ten tenders received, from £1,600 to £989.)

F. & C. Osler (Calcutta) have obtained contracts for the electric lighting of 40 camps at the Delhi Durbar, including the King's and many of the Indian chiefs' camps, the Delhi Circuit House, the Agra Circuit House and the two shooting camps in Nepal.

Commonwealth Contracts.—The Postmaster-General's Department in New South Wales is purchasing from the Western Electric Co. telephone apparatus for the Sydney exchange, at £745.

The Public Works Department of Western Australia has ordered electric pumping machinery from C. C. Humby & Co., at £5,518. 13s.

The Railways Department of Victoria have placed an order with W. T. Henley's Telegraph Works Co. for lead-covered paper-insulated telephone cable, at £162 per mile.

The British General Electric Co. (Sydney) recently received orders from the Australian Postmaster-General's Department for two motor-boosters for Sydney G.P.O. electric lighting plant.

The tenders of Lawrence & Hanson (£494) for wiring and supply of lamps and that of Noyes Bros. (£728) for electric light cables for the Small Arms Factory, Lithgow (N.S.W.), have been accepted.

BUSINESS NOTICES.

The registered offices of Richard Pape (Ltd.) have been removed to Belvedere Works, Belvedere, Kent, where all future communications should be sent.

Mr. H. N. Warburton, engineer, manager and secretary for the past 14 years of the Winchester Electric Light & Power Co., whose undertaking has been acquired by the Corporation, has decided to start in practice as a consulting engineer, with offices at 4, Upper High-street, Winchester, and 31, Great James-street, London, W.C.

Sale by Auction.—Messrs. Horne & Co., 35, Old Queen-street, Westminster, S.W., will sell by public auction at the Royal Arsenal, Woolwich, on Thursday, Oct. 24, some unserviceable and obsolete stores, including quantities of cast and wrought iron, steel scrap, brass, copper, cupro-nickel, lead, &c., some electric cable, a number of hydraulic and screw jacks, lathes, tools, metal filament lamps, &c. Lots may be viewed at the Royal Arsenal, Woolwich, on the Monday, Tuesday and Wednesday previous to and on morning of sale. Catalogues from the War Office, Whitehall, S.W., the Ordnance Office, Tower, E.C., and the Ordnance Office, Royal Arsenal, Woolwich. See also an advertisement.

Patents Development.—The proprietor of patent No. 18,842/1907, relating to "Means for receiving intelligence communicated by electric waves," wishes to dispose of the patent or to grant licences. Applications to Messrs. Cruikshank & Fairweather (Ltd.), 65 & 66, Chancery-lane, London, W.C.

Patents Guide.—We have received a copy of a pamphlet of 32 pages by Mr. Clarence W. Crossley on patent law and procedure. It contains some useful hints to inventors and manufacturers in regard to patent procedure and the development of patents. The pamphlet is published at 9d. nett by the author at 18, Pollard's Hill North, Streatham, London, S.W.

Imports.—The following are official values of electrical machinery material and apparatus imported into this country (*a*) during July, 1911, and (*b*) during the current year from Jan. 1 to July 31, and the increases or decreases compared with the corresponding periods of 1910 :—

Electrical machinery (*a*) £82,059 (increase £38,347), (*b*) £627,361 (increase £304,217); telegraph and telephone cables (*a*) £38,488 (increase £31,238), (*b*) £227,154 (increase £127,457); telegraph and telephone apparatus (*a*) £17,611 (increase £7,107) (*b*) £97,438 (decrease £68); other electrical wires and cables, rubber insulated (*a*) £8,198 (decrease £12,882), (*b*) £51,601 (decrease £68,794; with other insulations, £2,763 (decrease £22), (*b*) £21,193 (increase £3,833); carbons (*a*) £38 (decrease £1,545), (*b*) £72,579 (decrease £5,637); glow lamps (*a*) £833 (decrease £36,329), (*b*) £168,588 (decrease £152,139); arc lamps and electric searchlights (*a*) £119 (decrease £105), (*b*) £872 (decrease £53); parts of arc lamps and searchlights (other than carbons), (*a*) £514 (increase £1,965), (*b*) £62,127 (increase £21,935); primary and secondary batteries (*a*) £2,823 (decrease £545), (*b*) £25,276 (increase £1,337) total of electrical goods and apparatus, other than machinery and telegraph and telephone wire (*a*) £106,545 (decrease £13,719), (*b*) £795,065 (decrease £46,026).

Exports.—The exports of electrical machinery, material, &c. (*a*) during July, 1911, and (*b*) during the current year from Jan. 1 to July 31, and the increases and decreases compared with the corresponding periods of 1910, are as follows :—

Electrical machinery (*a*) £170,438 (decrease £1,814), (*b*) £1,002,053 (increase £110,378); telegraph and telephone cables (*a*) £44,769 (decrease £85,230), (*b*) £412,649 (decrease £617,444); telegraph and telephone apparatus (*a*) £18,999 (increase £832), (*b*) £151,396 (increase £51,262); other electrical wires and cables, rubber insulated (*a*) £29,404 (increase £444), (*b*) £233,409 (increase £5,086; with other insulations (*a*) £26,760 (increase £1,310), (*b*) £220,160 (increase £50,214); carbons, (*a*) £656 (decrease £543), (*b*) £10,078 (increase £217); glow lamps (*a*) £12,661 (increase £3,113), (*b*) £90,417 (increase £18,052); arc lamps and searchlights (*a*) £786 (decrease £816), (*b*) £10,917 (decrease £105); parts of arc lamps and searchlights (other than carbons) (*a*) £1,523 (increase £230), (*b*) £9,579 (increase £1,547); primary and secondary batteries (*a*) £10,839 (decrease £6,031), (*b*) £80,328 (increase £10,292). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire (*a*) £187,700 (decrease £82,195), (*b*) £1,542,133 (decrease £420,556).

BANKRUPTCIES, LIQUIDATIONS, &c.

The Helptophone Co. (Ltd.) is being wound up voluntarily. Mr. R. Evans Smith, 53, New Broad-street, London, E.C., is liquidator.

COMPANIES' MEETINGS AND REPORTS.

BULAWAYO WATERWORKS CO. (LTD.)—The chairman (Colonel Lockwood, M.P.) stated at the meeting last week that for the first five months of this year there was an increase in working profit of £1,800 for electric current compared with 1910. The number of consumers in May was 699, compared with 615 in May, 1910. The board consider that the outlook is distinctly encouraging. Considerable economies have been effected in working costs, and those, combined with increased demand should enable the company to arrive at a commercial success.

CENTRAL LONDON RAILWAY CO.—The chairman (Mr. H. F. Parshall) stated at the meeting last week that during the past half-year £51,464 had been expended on capital account, £40,282 in connection with the Liverpool-street extension, £2,617 on the high level subway connection with the City & South London Railway at the Bank station, and £779 the extra cost of replacing wooden platforms with stone. Work on the Liverpool-street extension was proceeding satisfactorily, and arrangements had been made that the work should be completed six months ahead of the original contract time, and will be ready next year. The high level subway at the Bank station was opened in May. Further capital expenditure, amounting to £310,485, was estimated to be required for the coming and subsequent half-years. During the past half-year they had carried over 20,000,000 passengers, a decrease of 658,609 compared with the corresponding period of 1910, which was undoubtedly due to increased motor 'bus competition along the company's line of route. Under the new organisation, without diminishing the efficiency, there had been a decrease in working expenses of £3,420, brought about by economies effected in all departments. After providing for debenture interest and other payments, and including the amount brought forward, the available balance was £75,655. A dividend on the ordinary stock at the same rate as last year (3 per cent.) would absorb £27,351, and the preferred would take £11,765, leaving £36,538. From this balance the directors propose to carry forward to the dividend suspense account £5,882 on account of the deferred stock at rate of 2 per cent. per annum, which would leave £30,655. During the three days of Coronation festivities they carried 730,000 passengers without a hitch of any kind. The staff worked admirably throughout that trying period, and the Board of Trade had intimated that H.M. the King had decided to grant Coronation medals to two members of the staff in appreciation of the splendid way in which the crowds were handled. The men all received an extra day's pay. On July 1 season tickets were inaugurated, and had been highly appreciated by the public, with satisfactory results to the company. Improvements were being effected at the stations, and a system of ventilation was being installed throughout the line.

Mr. MATHER asked whether the company's engineers had considered the question as to whether the time had now come to instal fresh plant in their generating station. He thought considerable economies could be effected by substituting for the generating engines a turbine plant.

The CHAIRMAN said the directors had given the subject their serious consideration, and had come to the conclusion that there was no justification whatever for scrapping their plant at Shepherd's Bush and installing turbines. They were using Allis Corliss engines of the very best type, and to-day they were running at less than 3 lb. of coal per kilowatt-hour, which was a very fine record for a power house. There was no station in the kingdom, and certainly there was none in the London area, which showed such good results as their Shepherd's Bush station.

CIA ARGENTINA DE ELECTRICIDAD.—The first report, from Oct. 1, 1909, to Dec. 31, 1910, states that $10,168 (gold) have been written off concessions account and a dividend of 5 per cent. declared on the preference shares. Sales of current produced $181,391 m/n. The authorised capital is $400,000, of which $11,400 is not yet issued.

Digitized by Google

HANKOW LIGHT & POWER CO. (LTD.)—The directors' report states that in March last tenders were accepted for a 300 kw. plant, which is now practically finished, and will, it is expected, be installed at the power station in time for the winter service. The lighting franchises from the English, French and Russian concessions have been formally assigned to the company. A new system of public lighting has been installed which is giving every satisfaction. There has been a steady increase in the private lighting and power department, and the receipts for the year ended March were £8,981. 5s. 10d., against £4,662. 19s. 7d. Working expenses for the year were 50·89 per cent. of total receipts, against 56·64 per cent. for the half-year to March 31, 1910. The credit balance of the trading account for the year was £4,228. 17s. 2d. After paying various amounts, there was a balance of £1,432. 18s., which reduces the debit balance to £2,513. 15s. 8d.

LANARKSHIRE TRAMWAYS CO.—At the meeting last week Mr. A. R. Monks said the result of the half-year's working of the system had been satisfactory. It had been decided to proceed with the extension to New Stevenston, as that would be completed before their powers lapsed, but the extensions to Bellshill and Mossend could not be proceeded with.

LIVERPOOL OVERHEAD RAILWAY CO. The directors' report states that gross revenue receipts for the half-year to June 30 amounted to £38,153. 17s. 2d. and working expenses to £27,229. 10s. 8d. The total number of passengers carried was 5,393,597, an increase of 303,517, producing an increase in receipts of £1,968. 3s. 1d. The bill for the consolidation of borrowing powers and for authorising the Mersey Docks and Harbour Board to guarantee payment of interest on debenture stock has passed both Houses of Parliament and awaits the Royal Assent. After paying debenture interest, &c., and adding balance brought forward (£4,246. 7s. 9d.) a balance of £10,841. 6s. 1d. is available for dividend. Out of this balance the directors recommend declaration of dividends at the rate of 5 per cent. on the preference and 1 per cent. on the ordinary shares, leaving £4,665. 9s. 1d. to be carried forward.

LONDON, TILBURY & SOUTHEND RAILWAY CO.—Mr. A. L. Stride, who presided at the meeting last week, stated that electric traction was working, as it did last half-year and the half-year before, at still lower and still better results, and earning more money for the expenditure on the other side of the account. The company had fought successfully the Greater London Bill. They did not know whether the Midland Railway Co. would be allowed to take over their line.

TYNESIDE TRAMWAYS CO.—At the meeting on Tuesday the Chairman (Dr. J. T. Merz) stated that there was a decrease in the car-mileage of 582, but the receipts per car-mile were 8·87d., against 8·273d. for the corresponding period of last year. They had carried 276,615 more passengers. The expenses had gone up somewhat. The balance brought forward was £456, and they carried forward a balance of £619, and they had increased the dividend from 1 to 1½ per cent. The loans had been reduced by £1,980, and they expected that in the course of the current half-year the remaining loans would be wiped out.

YORKSHIRE ELECTRIC POWER CO.—The gross profit for the half-year ended June 30 was £6,633. 8s. 2d., against £4,950. 3s. 6d. and £2,598. 12s. 11d. in the June half-years 1910 and 1909 respectively. The net profit for the same periods, after deduction of mortgage interest, was £4,137. 6s. 9d., £2,621. 17s. 8d. and £1,069. 17s. 11d. There has been a general increase in the sale of energy to all classes of consumers, including supply to local authorities and others holding electric lighting orders. Extensions of mains and plant have been made during the past half-year to meet new demands and the capital expended upon these has not yet become wholly productive. Further agreements have been made for the supply of energy to power users. The balance available (including amount brought forward) at June 30 was £13,612. 18s. 5d. and the directors recommend payment of the preference dividend to June 30 (£1,136. 7s. 4d.). The carry forward is £12,476. 11s. 1d.

NEW COMPANIES, MORTGAGES AND CHARGES, STATUTORY RETURNS, &c.

NEW COMPANIES.

COMPANIA DE ELECTRICIDAD DE VA PROVINCIA DE BUFNOS AIRES (LTD.) (117,118.)—Reg. Aug. 3, capital £1,000,000 in £1 shares, to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity and gas, manufacturers of and dealers in cables, wires, lines, lamps, dynamos, generators; railway, tramway, carriage and motor car proprietors; transmitters of telephonic and telegraphic communications outside the United Kingdom, &c., and to adopt an agreement with Alex. L. Secretan & Co.

FLYNN MANUFACTURING CO. (LTD.) (117,137.)—Reg. Aug. 4, capital £1,000 in £1 shares, to carry on the business of machinery and plant manufacturers, insulators of wire, wire coil and other metals, &c. Private company. First directors, C. Terry, A. E. Brambles, A. V. Terry, and T. J. Flynn.

MAGIC APPLIANCES (LTD.) (117,110.)—Reg. Aug. 2, capital £5,100 in 5,000 ordinary shares of £1 each and 2,000 deferred shares of 1s. each, to carry on the business of electrical and general engineers and contractors, manufacturers of and dealers in electrical and mechanical appliances, &c. Private company. First directors, W. Schmahl (man.), S. J. Atkinson, A. Stolberg and O. Ruoff. Reg. office, 6, Farringdon-avenue, London, E.C.

OHIO POWER SYND. (LTD.) (117,111.)—Reg. Aug. 2, capital £2,000 in £1 shares, to carry on the business of electricians, suppliers of electricity, &c. Private company. Reg. office, 123, Cannon-street, London, E.C.

STATUTORY RETURNS.

SHANGHAI ELECTRIC CONSTRUCTION CO. (LTD.)—In return to May 18 capital is £320,000 in £10 shares. All shares taken up. £317,000 paid. £3,000 considered as paid. Mortgages and charges, nil.

MORTGAGES AND CHARGES.

CORONA LAMP WORKS (LTD.)—Particulars of £2,000 debentures, created July 10 have been filed, amount of present issue being £200. Property charged: Company's undertaking and property, present and future, including uncalled capital. No trustees.

CUTTING BROS. (LTD.)—Particulars of £4,000 debentures, created July 12, have been filed, the whole amount being now issued. Property charged: Company's undertaking and property, present and future, including uncalled capital. No trustees.

VENNER TIME SWITCHES (LTD.)—Particulars of £5,000 debentures, created July 4, and secured by trust deed dated July 10, have been filed, the whole amount being now issued. Property charged: Company's undertaking and property, present and future, including uncalled capital. Trustee, R. B. Young.

RECEIVERSHIP.

G. W. CLARKE & CO. (LIVERPOOL) (LTD.)—W. L. Jackson, 51, North John-street, Liverpool, ceased to act as receiver or manager on July 28.

CITY NOTES.

MEMORANDA (Aug. 10).—Bank rate 3 per cent. (March 9, 1911.) Price of silver, 24 7/16d. per oz. Consols 78—78¼ for money and for account. Consols Pay Day, Sept. 1; Stock and Shares Continuation Days, Aug. 14 and 29; Ticket Days, Aug. 15 and 30; Pay Days, Aug. 16 and 31; Mining Shares Carry Over Day, Aug. 28.

PRICES OF METALS (London).—*Copper*, cash, 56 7/16; three months, 57 4/16. *Lead*, English, 14⅛—14⅜; Foreign, cash, 13 15/16—13 15/16; three months, £14. *Spelter*, 25 3/16—25 5/16. *Tin*, English, 194—196; Foreign, cash, 195½; three months, 188¾. *Iron*, Cleveland, cash, 46/9, three months, 47/7.

DUBLIN & LUCAN ELECTRIC RAILWAY CO. (LTD.)—The gross receipts for the half-year to June 30 were £3,455, and the directors propose payment of the preference dividend, carrying forward £444.

ELECTRIC SUPPLY CO. OF VICTORIA (LTD.)—This company's tramway and lighting receipts for April were £7,269.

MATHER & PLATT (LTD.)—The directors have declared an interim dividend on the ordinary shares of 5 per cent. (tax free) for the half-year to June 30, being at rate of 10 per cent. per annum.

OLDHAM, ASHTON & HYDE ELECTRIC TRAMWAYS (LTD.)—The directors have declared an interim dividend at the rate of 5 per cent. (5s. per share), less tax, on the ordinary shares for the past half-year.

PARA ELECTRIC RAILWAYS & LIGHTING CO. (LTD.)—The directors announce an interim dividend at the rate of 10 per cent. per annum (less tax) on the ordinary shares for the past half-year.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed Aug. 16 a special settling day in and have granted quotations to £100,000 5 per cent. debenture stock of the *Adelaide Electric Supply Co. (Ltd.)*, and fully and partly paid scrip for $4,500,000 5 per cent. first mortgage 30-year gold bonds of the *Mexican Northern Power Co. (Ltd.)* Quotations have also been granted to a further issue of £30,000 5 per cent. second mortgage debentures of the *Bombay Electric Supply & Tramways Co. (Ltd.)*, a further issue of 22,000 £5 fully paid shares of the *Chili Telephone Co. (Ltd.)*, and a further issue of £20,000 4½ per cent. first mortgage prior lien gold bonds of the *Montreal Water & Power Co.* The Committee have been asked to grant quotations to 20,000 £5 fully paid 7 per cent. first cumulative preference shares of the *Melbourne Electric Supply Co.*, 2,998 £10 fully paid 6 per cent. cumulative and 11,402 £10 fully-paid 6 per cent. non-cumulative preference shares and 27,050 1s. fully paid ordinary shares (in lieu partly of the 10,852 ordinary shares now quoted) of the *Notting Hill Electric Lighting Co.*, and a further issue of 5 per cent. 50-year mortgage bonds of the *Rio de Janeiro Tramway, Light & Power Co.*

VICTORIA FALLS & TRANSVAAL POWER CO. (LTD.)—We learn on good authority that the operations of this company are affording much gratification to the directors and officials, the prospects being exceptionally good. We believe we are correct in stating that the net profits on last month's working approximated £30,000. The called-up capital of the company, according to the last return, was £4,538,000—£1,000,000 in £1 ordinary shares, £1,838,000 in 6 per cent. cumulative preference shares, and £1,700,000 in 5 per cent. debentures.

THE ELECTRICIAN:

THE OLDEST WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY, SCIENCE AND FINANCE.

ESTABLISHED, First Series (Weekly), 1861; Second Series (Weekly), 1878.

No. 1,735. [No. 19. Vol. LXVII.] FRIDAY, AUGUST 18, 1911. PRICE SIXPENCE (by post, 6½d.), Abroad 9d., or 18 cents, or 90c., or 80pf.

CONTENTS OF THE CURRENT NUMBER.

NOTES 727
Arrangements for the Week .. 730
St. Marylebone Electricity Supply Accounts 731
Some Unexplored Fields in Electrical Engineering. By C. P. Steinmetz. Illus. .. 732
Some Alloys for Permanent Magnets. By C. F. Burgess and J. Aston 735
Variation of the Resistance of Selenium with the E.M.F. By J. Luterbacher. Illus. 736
Dubilier Wireless Telegraph Station at Seattle. Illus. 737
The Effect of Varying Proportions of Air and Steam on a Gas Producer. By E. A. Allcut, M.Sc. Illus. .. 740
Investigation of the Electrical State of the Upper Atmosphere. By A. J. Makower, M.A., W. Makower, M.A., D.Sc., W. M. Gregory and H. Robinson. Illustrated 742
Operation of Transmission Systems. *Discussion*..... 743
Previous Magnetic History as affected by Temperature. By Prof. E. Wilson and L. C. Budd. Illustrated 743
Ventilation of Turbo-Generators. By R. B. Williamson. Illustrated 744
LONDON COUNTY COUNCIL LOANS 746
REVIEWS 748
Lignes Electriques [Girardet and Dubi]. Reviewed by J. R. Dick. Automatische Fernsprechsysteme [Smith and Aldendorff].
Accuracy of the Bellini-Tosi Wireless "Compass" for Navigational Purposes. By L. H. Walter, M.A. Illus. 749
CORRESPONDENCE 751
Units of Resistivity (David Robertson).
Photometric Units and Nomenclature 752
Parliamentary Intelligence .. 753
Electric Winders 754

NOTES.

Labour Unrest.

ALTHOUGH there is a tendency, in certain quarters, to exaggerate the gravity of the situation, it cannot be denied that the strike epidemic gives cause for serious anxiety. No sooner is one dispute settled than another arises, and there is, apparently, no certainty that any given section will resume work, even on its own terms, unless other sections also receive satisfaction. So far as the electrical industry is concerned it will naturally be affected indirectly as is the case with other industries, but at present it does not appear to be threatened with upheaval. On the other hand, the railway situation is, at the moment of going to press, very difficult, although by no means hopeless. It might, perhaps, be opportune for the railways to consider how far it is possible to supersede hand signalling by automatic electric signalling, thus tending to reduce the inconvenience attendant on a great strike.

Progress in St. Marylebone.

OWING to the ease with which consumers can make alterations to their installations, such changes are apt to pass unrecorded by the supply authorities, and whilst considerable difficulty has always been experienced by the latter in keeping records of connections, &c., the introduction of improved forms of lamps during recent years has brought about such extensive changes in consumers' installations that several engineers have given up the attempt to keep even an approximate record of the apparatus installed. The Annual Report of the St. Marylebone Electric Supply Committee which accompanies the Statement of Accounts for the year ended 31st March last is, however, noteworthy for the careful and detailed particulars as to connections to the mains. It will be seen from the statistics on another page of this issue, where we analyse the past year's Accounts, that in March last 17 electric ovens, of an average capacity of 5 kw., and 150 other cooking utensils were connected to the St. Marylebone mains. At no distant date, therefore, Mr. A. H. SEABROOK will be in possession of valuable figures as to the cost, &c., of electric cooking.

WITH regard to heating, it is very gratifying to notice that the number of electric radiators on circuit increased during the past year by no less than 45 per cent., whilst electric irons seem to be jumping into popularity, since more than three times as many were in use in March last as compared with the number in use in the previous year. It is also surprising to notice the amount of electro-medical apparatus employed, 458 devices, requiring 313 kw., being connected to the mains. Much of the credit for recent progress is undoubtedly due to the Sales and Publicity Department of the undertaking, and whatever criticism may be brought forward as to the methods of this department, it must be admitted that the publicity side of electricity supply has need of development. In the case of an undertaking such as that of St. Marylebone, which is handicapped by abnormal capital expenditure and has not the opportunities for obtaining a large power load, much may be done by the encouragement of the domestic uses of electricity in reducing the capital charges per unit sold.

Digitized by Google

Mr. SEABROOK has made a good start in this direction, and the progress of his publicity department will prove interesting to other engineers.

Electrical Research.

As a rule, Mr. C. P. STEINMETZ is both original and entertaining, and his address to a joint meeting of two American societies, an abstract of which appears on another page, will therefore repay careful perusal. He spoke of many things, here a little and there a little, and in the main few people will be found to dispute his conclusions. Nevertheless, there may be some who will raise a protest concerning his complaint that "too often investigators have taken a pair of carbon terminals—since carbon terminals are mostly used in arc lamps—have put various things on them, and then written a treatise on the arc, without ever realising that whatever applies to the carbon arc does not necessarily apply to any other arc." This is unquestionably the truth, but it is not the whole truth. As a matter of fact, a very considerable amount of work has been done with metal electrodes of different kinds under widely varying conditions. It is perfectly correct that only a small corner of the field has yet been explored, but the work goes on, and it goes on in the right direction. Mr. STEINMETZ devoted considerable attention to the causes of lightning phenomena, mainly dwelling upon the accepted idea that the potential of a cloud, or a portion of a cloud, is raised by the coalescence of charged drops. Since the volume of a sphere varies as the cube of the radius and the surface as the square of the radius, it follows that if two equal drops of equal potential join together to form one, the potential of the new drop must be higher than that of either of the old drops.

IT is, perhaps, to be regretted that he did not indicate rather more clearly some possible methods by which his "unexplored fields" might be investigated. It is conceivable, of course, that he desired to draw the attention of engineers, as distinct from physicists, to these problems, in the hope that his audience might be disposed to undertake the work from the standpoint of the so-called practical man. Generally, however, the engineer has neither the time nor the equipment necessary for the investigation of these things, and it is often more convenient to leave it to the physicist to do the inquiry part of the business and then for the engineer to apply the results to practice.

Direct-current Traction at 1,500 volts. — According to "The Times Engineering Supplement" a contract for the electrification of two sections of the Piedmont Traction Co.'s system in North and South Carolina has recently been placed. This contract is especially interesting, as this is the first American railroad electrification project requiring apparatus wound for 1,500 volts direct current. One section, 35 miles long, extends from King's Mountain to Charlotte, N.C., and the other, 95 miles, extends from Greenwood to Spartanburg, S.C., with a 10-mile branch from Belton to Anderson. The power for both the electrified lines will be purchased from a local company and fed to the line through motor-generator sets in substations.

Electricity in Textile Mills.—In the list of members of the committee appointed to consider this question which we published in our issue of August 4th, the name of Mr. S. D. Schofield, electrical engineer of the Shipley Urban District Council, appeared as Mr. J. Schofield.

High Tension Power Transmission in California.—According to the "Electrical World," plans have been prepared by the Pacific Gas & Electric Co. for an additional hydro-electric plant of 71,000 H.P. This will cost about £2,000,000. The plans provide for the erection of two plants in the canyon of the South Yuba river, the first having a head of 1,647 ft.; this will develop 50,000 H.P. The second will use the same water, and will have a fall of 750 ft. developing 21,000 H.P. The overflow of water will be used for irrigation purposes. The Company now serves about 33,000 sq. miles in central California, and has about 1,100 miles of high-tension transmission line.

Results of High-Tension Continuous Current Railway Working.—The Washington, Baltimore & Annapolis Electric Railway was, when first opened, operated by single-phase current. Some years ago, however, the Company thought that better results might be obtained if continuous current at 1,200 volts were used. The change was completed in 1910. According to the "Electric Railway Journal," this high-tension system is reported to give every satisfaction and to be very economical. The maintenance of the single-phase cars cost 0·42d. per car-mile, but the new system only costs 0·09d., whilst the maintenance of the electrical equipment on the cars has fallen by 33 per cent. The total operating expenses for single-phase current were 11·9d. per car-mile, and have been reduced by the new system to 9·5d. Electrical delays have been reduced from 33 per cent. of the total to 19 per cent., although the total delays, including "power off," have been much reduced.

Telephonic Communication between London and Berlin.—It is stated that considerable interest has again been aroused in commercial circles at the prospect of a telephone service between London and Berlin, and the hope is expressed that the project will soon be realised. The new service to Berlin from London appears, from the reports, to be dependent upon a new land line which the French authorities have under construction to the German frontier, and when this is completed and linked up with the German line there will be direct communication between Berlin and London *via* the new cable which has been laid across the Channel by the British Government. There is also said to be a project on foot to establish a telephone line between Berlin and St. Petersburg, a project which has originated with a group of capitalists in the latter city. A Russian electric company has offered to construct the line for 10,000,000 roubles (£1,000,000). The route proposed is *via* Vilna, Warsaw, Lodz, Kalisch, &c.

The Best Position for Rail Bonds.—According to the "Engineer," the ideal place for placing rail bonds is underneath the angle plates. In this position the bond can be made very short, usually not over 10 in. Unless double bonding is required for conductivity, the practice is not recommended. It is better to use a single bond of sufficient capacity. For contact surface about 100 amps. per sq. in. is good practice. Angle plates should have a sufficiently large space between the plates and web of the rail, so that the bonds will not be pinched. In drilling holes in the rail oil must not be used. Sal ammoniac in water is a good lubricant. Immediately after drilling, the hole must be wiped out and the bond put in place without delay. When using a screw compressor a very small amount of flake graphite mixed with oil placed in the punch hole in the bond head will prevent the compressor plunger from cutting the bond, and enable the compressor screw to be turned up much more readily.

Cable Interruptions.	Date of Interruption.

Rubber Substitute.—The "Electrical Review and Western Electrician" states that the soya, or Manchurian bean, is claimed to make a capital substitute for rubber. The plant is an annual, and grows extensively in Japan and the East Indies. It somewhat resembles the kidney bean. When treated with nitric acid and alkalis, and subjected to great heat, it develops into a rubbery substance that can be vulcanised.

"Mazda" Wire Lamps.—Through the courtesy of the British Thomson-Houston Co., a party of press representatives visited Rugby on Wednesday last and were given an opportunity of inspecting the Company's lamp factory. The occasion provided an opportunity of announcing that the B.T.H. Co. has succeeded in producing a satisfactory drawn tungsten wire lamp. The visitors were shown how readily this material can be handled, especially when it was being wound on suitable supports on the lamp stem. They were also provided with samples of the drawn tungsten wire, and thus were able to test its toughness. The visit to the factory and the announcement made will be referred to more fully in our next issue.

Large Gas Engines for Steel Works.—The "Electrical World" states that the six gas engines being installed in the new power house of the Indiana Steel Co. at Gary, Ind., are the largest units ever constructed. They have a rating of 3,200 kw. each. The new engines are of the twin tandem double-acting Allis-Chalmers type, with cylinders 44 in. by 60 in. The engines will operate on blast-furnace gas, and are to drive alternators delivering three-phase current at 6,600 volts and a frequency of 25 to the power network of the Gary mills. Energy from the Gary power house will also be transmitted to the new plants of the American Bridge Co. and the American Sheet & Steel Co., west of Gary, and to the Indiana Harbour and South Chicago steel mills of the steel corporation. Three gas-engine sets similar to the new Gary units have been ordered for the Central Furnaces at Cleveland, Ohio, and two other units for the Joliet plant of the Illinois Steel Co.

Accidents in Mines.—The annual report for the year 1910 of Mr. R. A. S. Redmayne, Chief Inspector of Mines, which has just been issued shows that the total number of fatal accidents in the coal mines of the United Kingdom was 1,242, involving the death of 1,775 persons. Compared with 1909 there is an increase of 60 in the number of accidents and of 322 in the number of deaths. This total of 1,775 is the largest yet recorded. Of the 1,775 persons killed, 114 were under 16 years of age, as against 95 in the preceding year. Twenty accidents involving the death of the same number of persons were attributable to electrical causes. This is an increase of nine in the number of accidents and seven in the number of persons. Four of these accidents, involving the death of the same number of people, occurred on the pit bank. In metalliferous mines there were 38 fatal accidents which caused 43 deaths. Compared with 1909 the number of fatal accidents is the same, whilst there is an increase of three in the number of deaths. At quarries there were 80 fatal accidents, which resulted in 84 deaths. Compared with 1909 there is a decrease of three in the number of accidents, while the number of deaths remains the same. As regards non-fatal accidents which disabled the injured for more than seven days, the number in coal mines was 58,565, in metalliferous mines 1,578 and in quarries 5,156. Compared with 1909 these figures show increases of 5,736, 62 and 319 respectively. Of these 44, 1, and none respectively were due to electricity.

Electrically-driven Conveyors for Unloading Bananas.—According to the "Electrical World," at New Orleans and Mobile the United Fruit Co. makes use of motor-driven machines of the marine-leg type for unloading bunches of bananas from the holds of its vessels, saving much of the time, labour and damage to the fruit that was formerly occasioned by hand unloading. From an extension boom projecting over the water's edge a 35 ft. vertical marine leg is dropped into the hatch of the vessel drawn up to the wharf. Sprocket wheels on the marine leg and stationary portions of the unloader carry a pair of chains 4 ft. apart, between which, on cross-bars, is stretched a canvas strip so arranged with slack as to form pockets at 3 ft. intervals. The four machines at New Orleans have 92-pocket belts, and each is driven by its own 15 H.P. induction motor. These machines are individually capable of unloading 2,500 bunches of bananas per hour, the bunches weighing from 60 lb. to 120 lb. each. In the hold of the vessel the conveyors are filled from three levels, each level loading into every third pocket of the conveyor, the speed of the latter being too high to permit filling successive pockets from a single position. After reaching the back or dock end of the conveyor the pocket chain passes over a flat roller, which gently discharges the bananas on to a moving belt running along to the cars where the fruit is loaded for shipment by rail. At New Orleans the level of the Mississippi varies periodically by about 14 ft., and the unloaders must be designed for this variation as well as to reach the hatches of any ordinary vessel. The suspended marine leg is supported from an auxiliary boom hinged to the main boom, so that by making a jack-knife bend practically any hatch level or distance from the wharf can be negotiated. The manipulation of the booms and hoists and the side travel of the huge machine along the dock front are all operated from friction clutches on the main conveyor-motor shaft. Within three to five minutes after the vessel's hatches are made ready the machines can be placed in position and the unloading begun. Ships are unloaded in from 90 minutes to seven hours, depending, of course, on the size of their cargo. The four machines at New Orleans working together can unload 10,000 bunches of bananas per hour. Besides expediting the work of unloading and saving labour, the machines effect their most important economy in preventing damage to the fruit. Current is supplied from plug connections placed on the side of the quay.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. L. H. Walter contributes an article on the "Accuracy of the Bellini-Tosi Wireless Compass for Navigational Purposes."

We describe an interesting wireless telegraph station erected by Mr. W. Dubilier on Puget Sound, near Seattle, U.S.A.

At a joint meeting of the Franklin Institute and the American Institute of Electrical Engineers, Dr. C. P. Steinmetz contributed a Paper on "Some Unexplored Fields in Electrical Engineering."

We give an abstract of a Paper read by Messrs. A. J. Makower, W. Makower, W. M. Gregory and H. Robinson before the Royal Meteorological Society on "Investigation of the Electrical State of the Upper Atmosphere."

Prof. E. Wilson and Mr. L. C. Budd read a Paper before the Physical Society on "Previous Magnetic History as Affected by Temperature."

Mr. R. B. Williamson recently read a Paper before the National Electric Light Association on the "Ventilation of Turbo-Generators."

We analyse the accounts for the year ended March 31, 1911, of the St. Marylebone electricity department.

Abstracts of the accounts of several municipal electricity and tramway undertakings are given in another column.

Parliamentary.—The Telephone Transfer and Pacific Cable Bills have passed through the Committee stage in the House of Commons.

Legal.—The Osram Lamp Works (Ltd.) have been successful in an action for infringement of patent against the British Tungsten Lamp Co., and an order has been made (by consent) restraining defendants from further infringement.

Companies' Meetings, Reports, &c.—At meetings of the London Electric and Metropolitan District Railway Companies last week Lord Geo. Hamilton gave interesting particulars of the development of the traffic on these lines. Other meetings which are reported include those of the Lancashire & Yorkshire Railway, the Liverpool Overhead Railway and New General Traction Companies.

PERSONAL NOTE.

The following notice appeared in "The Times" of Tuesday last: Parshall-Johnson.—On August 5th, at Folkestone, Horace Field Parshall, D.Sc., M.Inst.C.E., of 59, Netherhall-gardens, N.W., to Bertha Johnson, of Scruton, Yorkshire.

APPOINTMENTS VACANT AND FILLED.

A lecturer and instructor in telephony (for one evening) and a teacher of manipulative telegraphy (for two evenings per week) are required at the Wimbledon Technical Institute. Applications to the Principal, Gladstone-road, Wimbledon. See an advertisement.

Marconi's Wireless Telegraph Co., Watergate House, Adelphi, London, W.C., have vacancies for two electrical engineers in Spain. See advertisement.

The Committee of East Ham Technical College invite applications for the post of instructor of the evening classes in telegraphy and telephony. Salary 10s. 6d. per evening. Applications to Mr. W. H. Barker, B.Sc., Technical College, East Ham.

The Borough of Aston Manor Education Committee require an assistant master qualified to teach electrical and mechanical engineering and mathematics (especially practical). Commencing salary £160. Applications to Mr. H. Norwood, Education Offices, Aston Manor, near Birmingham, by Aug. 28.

It is announced that Mr. Edward Crabb, C.B., has been appointed second secretary to the Post Office in succession to Sir A. F. King, K.C.B., promoted to be secretary. In view of the approaching transfer of the National Telephone Co.'s business to the Post Office, and in order to secure a proper co-ordination of the work of the Telegraph and Telephone Departments, the Postmaster-General has established a post of third secretary with supervision over those departments. Mr. A. M. Ogilvie, hitherto assistant secretary in charge of the Telephone Department, has been appointed third secretary. Mr. A. B. Walkley and Mr. L. T. Horne have been promoted from principal clerks to be assistant secretaries to the Post Office.

Mr. G. Allbut has been appointed electrical engineer to the Newcastle (N.S.W.) City Council.

Mr. C. H. Lydall has been appointed Argentine representative of Messrs. Merz & McLellan.

Mr. R. E. Armstrong has been appointed charge engineer at the Greenwich power station of the London County Council.

INSTITUTIONS AND SOCIETIES.

American Institute of Electrical Engineers.—It is announced that Mr. R. W. Pope, who has held the post of secretary of this Institute for the past 26 years, resigned his position on the first day of this month. Mr. Pope became connected with electrical work at the early age of 14, and until 1882 was in the employ of various telegraph companies in the United States. In the latter year he was appointed manager of the Union Electric Mfg. Co. of New York, and in 1884 took over the associate editorship of the "Electrician and Electrical Engineer." In 1885 he was appointed to the position he has just resigned, the American Institute of Electrical Engineers having been formed the year before. The Board of Directors have appointed Mr. Pope honorary secretary of the Institute.

Institution of Civil Engineers.—The Council of this institution have made the following awards in respect of students' Papers read during the session 1910-1911: The "James Forrest" medal and a Miller prize to Mr. D. Hay, B.S.., and Miller prizes to Messrs. D. A. Howell, R. Bonner, G. F. Walton, R. G. Parrott, E. E. Farrant, A. C. Dean, B.Sc., H. W. Coales, A. H. Meade, A. C. Swales and H. J. F. Gourley, B.Eng.

EDUCATIONAL NOTICES.

University of Manchester.—A complete theoretical and practical training is given at this University to students preparing for the higher positions in the electrical engineering profession. The subject may be taken as part of the course preparing for the B.Sc. degree in both the Honours Schools of Engineering and of Physics, and a special course has also been arranged extending over three years, and preparing for the certificate in electrical engineering. The John Hopkinson laboratories (which are being extended) and dynamo house are fitted with modern electrical machinery, and good facilities are offered for educational and research work. The 1911-1912 session commences on Oct. 3. Prospectuses may be obtained from the Registrar.

University of Sheffield.—The faculty of applied science comprises the departments of engineering, metallurgy, coal mining and architecture. The courses in engineering or in metallurgy extend over three years and prepare respectively for the degree of B.Eng. or B.Met. of the university. The lecture courses commence on Oct. 4, and the technical laboratory courses on Sept. 18. Prospectuses and other particulars from the registrar, Mr. W. M. Gibbons.

University of Durham.—Armstrong College, Newcastle-upon-Tyne.—The 1911-12 session commences Sept. 25. There are departments of mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars may be obtained from the secretary, Mr. F. H. Pruen, M.A.

Imperial College of Science and Technology.—During the 1911-12 session an advanced course of instruction on the systematic design and manufacture of dynamo-electric machinery will be given at the City and Guilds (Engineering) College, Exhibition-road, London, S.W., under the general supervision of Prof. T. Mather, F.R.S.

The course is intended for post graduates and other fully qualified students, the number of whom will be limited. The lectures (about 45 in number) will be delivered during the first half of the session by Mr. W. E. Robson, M.I.E.E., and the practical work will commence in October and continue throughout the session. Ratings, frame sizes, windings, &c., for complete lines of machines will be considered in detail, as well as works organisation for systematic manufacture. In addition to lectures, practice in designing, estimating and drawing office work will be given, and advanced laboratory work relating to the limiting conditions existing in modern machines. It is intended that the course should deal with present-day problems in design, construction and testing in a thoroughly practical manner, and an experienced designer and draughtsman, who has been specially engaged for the purpose, will devote his whole time to the drawing office work in connection with the course. Applications for admission to the Dean of the College, Exhibition-road, London, S.W.

City and Guilds Technical College.—This college provides a scientific training for students preparing to become electrical and mechanical engineers or chemists, and for engineering pupils who desire to supplement their practical training by a two years' course of instruction in the principles of engineering science. There are also arrangements for three-year courses in engineering. Particulars at the college, Leonard-street, City-road, London, E.C., or from the City and Guilds of London Institute, Gresham College, Basinghall-street, London, E.C.

Glasgow and West of Scotland Technical College.—The diploma of the college is granted in the departments of civil, electrical and mechanical engineering, mining, naval architecture, chemistry, metallurgy, mathematics and physics, building and textile manufactures. The courses of study usually extend over three sessions and holders of the diploma are eligible for the degree of B.Sc. in engineering of the University of Glasgow, after attendance for at least one session at prescribed university classes. The laboratories are well equipped, and facilities for research are afforded in the departments of physics, electrical engineering, chemistry, metallurgy, mechanics, &c. The preliminary examination begins on Sept. 11, and names of candidates must be sent in by Sept. 1. The day classes begin Sept. 26 and the evening classes Sept. 21. Calendar (by post 1s. 4d.) and prospectuses (gratis) will be sent on application to the Director.

City of Bradford Technical College.—At this college there are full-day courses qualifying for the college diploma in civil, mechanical and electrical engineering. The next session commences Sept. 1. The new power house, especially arranged for experimental and educational work, will be opened during the session, and the equipment of the electrical engineering laboratories and machine room has also been considerably extended and brought up to date. Calendar, containing particulars of all courses, on application to the director of education, Mr. A. C. Coffin.

ARRANGEMENTS FOR THE WEEK.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued:—

Head-quarters will be closed for instruction, but will be open for all work as under until further orders:—

Monday to Friday, 10 a.m. to 4 p.m.

Saturday, 10 a.m. to 12 noon.

Digitized by Google

ST. MARYLEBONE ELECTRICITY SUPPLY ACCOUNTS.

In view of the fact that the total sales of electrical energy during the year ended March 31 last showed an increase of 14½ per cent., compared with the figures for the previous year, it will be seen that the St. Marylebone electricity undertaking is making considerable progress. Both private and public lighting and power and heating have contributed to the above increase, the respective figures for the two years being as follows :—

	1911.	1910.
Private lighting	9,151,553	8,447,124
Public lighting	1,397,585	743,002
Power and heat	1,787,818	1,586,333

The large increase in the output for public lighting is due to the Electricity Department having taken over the lighting of the remainder of the street lamps of the Borough; whilst the fact that the number of consumers has increased from 7,479 to 8,098—a larger growth than for many years past—also testifies to the activity of the Department.

The average price received was: for private lighting 3·826d. per unit, and for power 1·477d., the average for the whole of the private supply being 3·44d.

It is very gratifying to notice the steady improvement of the load-factor. For the past year this was 16·9 per cent., as against 15·7 per cent. in 1909-10, 14·5 per cent. in 1908-9, and only 11·8 per cent. in 1906-7. Under these conditions it is not surprising that the cost per unit sold has shown a very satisfactory decrease, and from our analysis below of the past year's accounts, it will be seen that the total cost, excluding capital charges, is now down to 1d. per unit sold, this figure including the cost of the Sales and Publicity Department.

It is, however, as regards capital charges that the undertaking is most severely handicapped. Indeed, it will be noticed that these charges are more than double the total of all the other items, and bring the actual cost of supply to 3·23d. per unit. It may be noted that the present figure for the capital charges, viz. 2·23d. per unit, compares with 2·52d. in the previous year, and 3·01d. in 1908-9, so that progress is being made. These figures emphasise the importance of improving the load-factor of the undertaking, and the present policy of Mr. A. H. Seabrook, of popularising the use of electricity for all purposes, is evidently making a satisfactory impression on these abnormal capital charges.

The statistical tables and diagrams which accompany the Report of the Electric Supply Committee and the Statement of Accounts for the past year are of particular interest in this connection, and are noteworthy for the amount of detail which they contain, very full information being given as to the nature of the connections to the supply mains. The amount of heating apparatus on circuit on March 31, 1911, was as follows, the increase during the previous twelve months being also given :—

Heating and other apparatus on circuit.	March, 1911. No.	Kw.	Increase. No.
(a) Radiators	1,323	1,456	413
(b) Cooking apparatus { Ovens	17	84	52
(b) Cooking apparatus { Sundries	150	121	52
(c) Irons	516	172	356
(d) Medical apparatus	458	313	31
(e) Sundry apparatus unclassified	644	596	73

The number of motors connected to the mains at the same date was 870, an increase of 138 during the year, the total horse-power connected being 3,254. Of the above motors 3 are on hire. An interesting feature also is that the number of repayment supplies has increased by 222, and is now 719.

In connection with the Sales and Publicity Department, the total expenditure for the year was £19,171, this including £4,208 for salaries, £1,679 for establishment expenses, stationery, etc., and £11,228 for goods and works carried out for consumers. The receipts by this Department totalled £16,959, £5,484 of this being for sale of apparatus, &c., to consumers. The net cost of the Department for the year was therefore £2,212; which represents less than 1½ per cent. of the revenue obtained from the sale of current.

It should be noted that this cost also includes that of keeping business already obtained. A special feature has been made of this section, the "satisfied consumer" being the aim in view. An idea of the importance of this part of the Department's work can be gathered from the fact that for quite a month at the end of each quarter practically the whole of the staff is employed in settling account queries and complaints. In every case, in addition to providing a satisfactory explanation, an improved scheme of lighting is drawn up for the consumer.

The Report states that much has been done by the Department in preparing the ground for the application of electric cooking and heating, which offers great possibilities. Finally, the Committee claim that the results show conclusively that the statement made and reiterated that the Department cuts prices and unfairly competes with contractors is without foundation in fact.

We give below an analysis of the various items of expenditure and revenue in the Accounts for the year ended March 31, 1911, together with the cost per unit sold for each item :—

		Cost per unit sold.
Generating Costs.		
Fuel	£13,748	0·27d.
Oil, waste, water, &c.	541	0·01d.
Wages at station	5,228	0·10d.
Repairs and maintenance	2,558	0·05d.
Miscellaneous	148	0·00d.
Total Generating Expenses	£22,223	0·43d.
Distribution Costs.		
Wages	£1,331	0·02d.
Repairs to mains	1,915	0·04d.
Repairs to meters, &c.	1,409	0·03d.
Repairs at sub-stations	1,175	0·02d.
Salaries and establishment expenses	1,897	0·04d.
Total Distribution Costs	£7,727	0·15d.
Management Costs.		
Salaries	£4,994	0·10d.
Meter reading	679	0·01d.
Stationery and printing	601	0·01d.
General establishment charges	1,474	0·03d.
Central establishment charges	350	0·01d.
Law and parliamentary charges	784	0·01d.
Insurance	502	0·01d.
Special expenses	273	0·01d.
Total Management Costs	£9,657	0·19d.
Rents, Rates and taxes	£4,552	0·09d.
Public lighting maintenance	5,210	0·10d.
Sales, publicity, &c. (£19,171 less £16,959 revenue).	£2,212	0·04d.
TOTAL COSTS (*ex.* capital charges)	**£51,581**	**1·00d.**
Capital Charges.		
Interest	£75,617	1·47d.
Sinking fund	37,938	0·74d.
Miscellaneous	169	0·00d.
Part cost of installing street lamps	800*	0·02d.
Total Capital Charges	£114,524	2·23d.
TOTAL COSTS (*inc.* capital charges)	**£166,105**	**3·23d.**
Revenue.		
Sale of current	£156,539	3·04d.
Public lighting (*inc.* maintenance)	13,769	0·27d.
Meter rents	6,179	0·12d.
Rent of property (*less* repairs)	616	0·01d.
Bank Interest	553	0·01d.
Miscellaneous	538	0·01d.
TOTAL REVENUE	**£178,194**	**3·46d.**
Balance	£12,089	0·23d.

This balance is disposed of as follows :—£2,166 is allocated to expenditure in the nature of capital; £1,192 to motors, &c., supplied to consumers; £1,183 to sundry improvements and special works; £48 to capital expenditure written off; £788 to bonuses to staff; and the remaining £6,712 is unappropriated.

The capital expenditure on the undertaking during the past year was £23,884, due almost entirely to the extension of

* Balance (£6,525) charged to General Rate.

mains in connection with the street lighting, and to service lines and meters for new consumers. The total capital expenditure to March 31 last was £2,061,160, made up as follows:

Purchase of undertaking	£1,399,935
Lands	41,011
Buildings	72,563
Machinery	193,415
Accumulators	15,680
Mains and services	136,609
Meters	19,108
Electrical Instruments	423
Change of pressure and system	149,928
Tools	2,873
Furniture	940
Engineers' commission	23,460
Cost of order and Acts	5,215
TOTAL	£2,061,160

SOME UNEXPLORED FIELDS IN ELECTRICAL ENGINEERING.*

BY C. P. STEINMETZ.

Summary.—The author suggests a number of electrical phenomen[a] which require further investigation. Among these are: the curren[t] distribution in a conductor conveying alternating current, lightning discharges, the conduction of gases and vapours, the loss of energy by a cyclic change of magnetism, magnetic alloys. Two vast fields in which increased knowledge is of immediate industrial importance are: the properties of materials beyond the elastic limit and transient phenomena resulting from the readjustment of the stored energy of systems.

A lot of work has been done along many lines since the early days of electrical engineering and a lot of different fields have been uncovered; but there are larger fields still unexplored and there are regions that are still unknown. For example, there is no simpler and

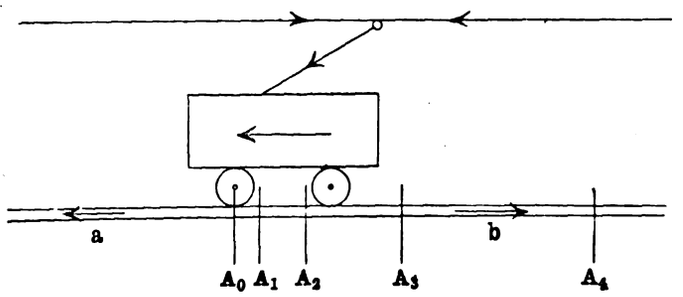

FIG 1.

apparently better known phenomenon than the resistance of a conductor. A conductor has a definite resistance which varies with the temperature, &c. With alternating current the resistance apparently increases in large conductors, because the current flowing in the conductor is not uniform throughout the entire section. We can calculate the phenomena of the lack of uniformity of the current density in the conductor for the case where the current density is not yet very un-uniform (the current density at the centre being only 5 to 10 per cent. lower than at the periphery) and get an approximation which is satisfactory for all purposes of electrical engineering. There is also the other extreme, where the current density in the middle of the conductor is practically zero, and the current is limited to a thin shell on the outer surface as in the rail return of the single-phase railway, or in ordinary conductors at very high frequencies, as with lightning discharges. This case we can also calculate, determine the current distribution in the conductor, the apparent penetration and the effective resistance of the conductor, with an approximation as close as our knowledge of the constants of the material, the conductivity and permeability permits. But when you come to the intermediate and probably most interesting case, where there is current even in the centre of the conductor, but a material difference in the current density between the outside and the centre of the conductor, we find as solution an infinite series, which in this case converges so slowly as to be practically useless, and this case thus is still practically unexplored.

* Abstract of a Paper presented at a joint meeting of the electrical section of the Franklin Institute and the Philadelphia Section of the American Institute of Electrical Engineers.

Another unexplored phenomenon of every-day occurrence: there are many thousands of trolley cars running all over the country with a direct-current supply of about 500 volts, and rail return. While the car passes along the track, the current flows from the wheels down into the rails, and then in the rails to the station, as sketched diagrammatically in Fig. 1. At the point A_0 the current enters the rail from the wheel. To the left of this point, it flows towards the left, as indicated by the arrow *a*. To the right of A_0, it is supposed to flow towards the right, as indicated by *b*, and at the point A_0 the current in the rail thus is supposed to reverse. However, the current cannot instantly reverse in the entire rail section, but the same screening effect of the magnetic field in the conductor, which causes unequal current distribution with an alternating current, makes it impossible for the current inside of the conductor to reverse instantly, and in the first moment, the reverse current *b* thus flows only on the very top surface of the conductor and only gradually penetrates deeper into the conductor, and before the current flows uniformly throughout the entire rail section in the new direction *b* the car has moved hundreds or even thousands of feet. Thus, the current distribution in the rail behind the moving car, in the successive sections A_1, A_2, ... is as indicated approximately in Fig. 2, where the black or shaded portion of the rail shows the section in which the current has already reversed, the unshaded portion the unreversed part, that is, that part in which the current still flows in opposition to the resultant current flow, is running forwards instead of backwards. The obvious result is an increase of the effective resistance of the rail return, which immediately behind a high-speed car may be very considerable. Still this phenomenon, which occurs daily all over the country, has never been investigated, not even been recognised in its existence.

In some fields of electrical engineering or of electrical science we might almost say that we know less now than we knew, or rather believed we knew, a quarter of a century ago. There are things which had been investigated a quarter of a century ago and which were explained in a satisfactory manner to our limited knowledge in the early days, but this explanation does not seem satisfactory now, with our greater knowledge. A curious example we might cite from the text-books on natural history. There are supposed to be some fishes which are capable of giving electric shocks, fishes which have

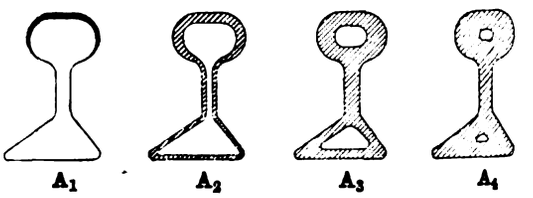

FIG. 2.

an organ which generates electricity; it has been described as being constituted like a Volta-pile. That theory was quite acceptable 25 years ago, but is not satisfactory now. To give a severe shock would require about 500 to 1,000 volts, and it is not intelligible how such voltage could be generated in the conducting animal tissue, without being short-circuited. Furthermore, the fish is immersed in water, which is a fair conductor, especially sea water, and 500 volts or more would produce hundreds of amperes in the surrounding water, representing hundreds of kilowatts, and it is not intelligible how such a large power could be generated even momentarily. Just why that phenomenon has not been investigated by electrical engineers we do not know; especially when considering that one of the electric fishes, *raja torpedo*, lives in the Mediterranean and is frequently caught on the Italian shores, that is, within easy reach of engineers.

But we do not need to go so far from home; right at hand we have some of the most important uninvestigated phenomena of electricity. The thunder-storm, the lightning, and so forth. Speculations were made in the early days as to how the clouds became charged, and as then the only method of producing electricity was by friction, it was said it might be the friction of the vapour through the air, or the rain drops through the air, or some other form of friction. That explanation used to appear satisfactory, but with our present knowledge of dielectric phenomena, it is not satisfactory any more. It was thought that lightning was the discharge from the cloud to the ground. That means that the electric field between the cloud and the ground must be beyond the breakdown strength of air. In a uniform field, the breakdown strength of air is about 75 000 volts per inch, or nearly a million volts per foot. Even if the cloud is only 1,000 ft. above ground, this would require a thousand million volts. If there were

Digitized by Google

an electrostatic field between the cloud and the ground of a thousand million volts extending over the whole area of the thunder cloud, this would represent such an immense amount of electric energy that it is inconceivable how any reasonable source of energy can produce it; how it can exist without having a destructive effect far beyond anything known of lightning. Furthermore, a uniform field cannot well exist between clouds and ground, on account of the unevenness of the ground surface.

Let us look into another conception, not a uniform electrostatic field, but an un-uniform field, like that of the discharge between points. With long striking distances between points, the average gradient is about 170,000 volts per foot. This would require only 170 million volts between a cloud 1,000 ft. high, and the ground. This would be more reasonable. It would not require such an unreasonably vast amount of stored electric energy. But we know that in such an un-uniform field the spark is preceded by a brush discharge covering more than half the distance. Thus, lightning should be preceded by a brush reaching down from the cloud and up from the ground, for several hundred feet. Now such an enormous brush has never been observed, and is inconceivable; the brush discharges occasionally observed at points during storms are only a few inches long. Furthermore, a 300 ft. brush is inconceivable, because the resistance of the ground is not low enough to conduct the energy necessary to maintain such a brush discharge. Furthermore, most of the lightning discharges are not between the cloud and the ground, but are internally in the clouds, frequently reaching the length of several miles.

With our present knowledge we must consider as the most probable explanation—although not certain by any means—that the lightning discharge is the phenomenon of the equalisation of internal electric stresses in the cloud, and is analogous to the splintering or breaking of an unevenly stressed brittle material, like glass. But how do those uneven electrostatic stresses originate in the cloud, and how do they reach such values as to cause internal equalisation by rupture?

It is not so difficult to make a preliminary estimate of the building up to very high and uneven voltage distribution in the cloud as soon as you have assumed some initial voltage. We do not know where the initial voltage comes from, but we must accept the fact that there is normally a voltage gradient in the air, a potential difference between different altitudes which may amount to a hundred volts or more per foot. In the air 100 ft. above the ground there may be a potential difference against ground amounting to thousands of volts. Possibly, this potential gradient in the atmosphere may even be of cosmic origin: the earth having a high negative potential against our solar system, against the universe, which would mean that there must be a positive voltage gradient from the surface of the ground into space.

If condensation takes place in the higher regions of the atmosphere, rain drops form, minute drops at first, which necessarily must be at the potential of the air in which they form. That means they have a potential difference against the ground, and therefore an electrostatic charge against the ground corresponding to this potential difference. Assuming now that many of these minute rain drops conglomerate to larger drops, it means that many small condensers conglomerate to one condenser, which is somewhat larger in capacity than each component, but very much smaller in capacity than the sum of the capacities of its components. But it contains all the electrostatic charges of the rain drops, and at the much smaller capacity the same charge gives a higher potential difference. Conglomeration of minute drops into larger ones thus must give a great increase of potential difference against ground. We know the clouds are not uniform in density, and where the density is greatest conglomeration of condensed drops takes place to a much greater extent, building up to a much higher voltage, and thereby between the parts of the cloud of different density, the light and the dark portions, potential differences must appear and increase with increasing condensation, until somewhere the disruptive gradient is passed, equilisation occurs by a lightning discharge, and then the same play repeats again and again. Lightning discharges, then, are the result of the voltage inequalities produced in the clouds by the unequal rate of conglomeration of rain particles due to the unequal cloud density. In agreement with this is that heavy lightning strokes are usually followed by a heavy downpour of rain; in reality they are preceded and caused by it, but it takes time for the rain drops to come down.

Let us assume now that the process is reversed, and after conglomerating to high voltages the rain drops evaporate again. Since gases apparently do not carry electrostatic charges, the rapidly dwindling rain drop retains its entire charge, hence must rise in potential, and finally must discharge, and this progressive evaporation of the rain drops must also result in the building up of potential differences and therefore the formation of lightning, and this may explain the two forms of lightning—that accompanying rain-storms and thunder-storms, and the so-called "heat" lightning. The former is the result of condensation and conglomeration, the latter the result of evaporation of rain drops.

Again, we must abandon the conception of the theory of electrostatics of the early days—which still largely is used in theoretical text-books—as incorrect and useless. Capacity is not the capability of the conductor to store electric quantity, but is the ratio of the number of lines of dielectric force to the E.M.F. which produces them; "charging current" is no more a current charging the conductor with electricity than the "inductance voltage" is a voltage charging the conductor with magnetism; the former, as "capacity current," supplies the energy stored in the dielectric field, just as the inductance voltage supplies the energy stored in the magnetic field, and dielectric and magnetic phenomena are very largely analogous and treated in the same manner and with the same simplicity.

Next, as to the conduction of gases and vapours, it is a field in which an enormous amount of investigation has been carried on in late years by the physicists, so that it may almost be called the best explored branch of modern physics. Unfortunately, there has been very little, if any, benefit from all this work to the electrical engineer. If you ask some simple engineering question, as, for instance, you have a Geissler tube, 4 cm. diameter and 10 m. long, filled with nitrogen gas under 0·1 mm. pressure. What will be the voltage required to pass a current through the tube; what will be the amount of light given by it; and how will the voltage vary with the current and with the gas pressure? The answer is unknown.

We now have some data on the electrical constants of gas conduction, and our knowledge is rapidly increasing by the work of engineers, who finally, as in other fields of research, despairing of ever getting the scientific investigators to drop metaphysical speculations long enough to determine physical facts, have started to investigate the engineering facts themselves.

The same applies to arc conduction, though arc conduction has been investigated by the engineers for a much longer time, and more is known about it. Much of the work done on arc conduction is worse than useless, by unjustified generalisation. Too often investigators have taken a pair of carbon terminals—since carbon terminals are mostly used in arc lamps—have put various things on them, and then written a treatise on "the arc," without ever realising that whatever applies to the carbon arc does not necessarily apply to any other arc.

The conductor in the Geissler tube is the gas which fills the space between the electrodes, and the material of the latter is therefore of secondary importance; but the phenomena, as the voltage, the colour and the spectrum of the light, &c., essentially depend on the nature of the gas in the space between the electrodes, and on its pressure. In the arc, however, the conductor is a stream of electrode vapour; the material of the electrode therefore is of fundamental importance on the voltage, luminosity, colour and spectrum of the arc stream, while the surrounding gas is of secondary importance only. The conducting vapour stream, or "arc stream," usually is at the boiling point of the electrode material. The carbon arc thus is the hottest arc. The dielectric strength of gases decreases with increase of temperature, and at the temperature of the carbon arc stream has fallen below the voltage drop in the arc stream, so that in the carbon arc all the phenomena resulting from the dielectric strength of the vapour stream are absent, since the surrounding air has a disruptive strength less than the supply voltage of the arc. Nearly the same is the case with a few other very hot arcs. The carbon arc thus is not a typical arc, but is one of the extremes in a series of arc conductors, of which the other extreme probably is the mercury arc, as the coldest arc. The latter thus gives the phenomena of the dielectric strength of the arc stream most pronounced.

As the phenomena of arc conduction essentially depend on the temperature of the arc stream, that is, the boiling point of the electrode material, typical conditions we can expect only from electrode materials having boiling points intermediate between the extremes, carbon and mercury. Such are many metals, as iron, copper, &c. The iron arc thus is a typical arc, but not so the carbon arc. In the study of a typical arc we find that the vapour stream, which conducts the current, issues from the negative terminal, as shown by its spectrum, and by the character of the arc; the latter depends on the material of the negative terminal, but is unaffected by any change of the positive terminal. The vapour conductor of the arc is moving rapidly from the negative terminal towards the positive, and is a conductor in the direction from the negative terminal to any point reached by the arc stream, which is positive towards the negative arc terminal, but is non-conducting with regard to any body negative towards the negative arc terminal. The arc stream is a unidirectional conductor, and is extensively used for rectification.

The voltage range, within which an arc stream is non-conducting towards a negative body, or, as usually called, the "rectifying vol-

Digitized by Google

tage range of the arc stream," is determined by the disruptive strength, and thus is a function of the temperature. It is many thousand volts with the low temperature mercury arc, is still several hundred volts with the iron or copper arc, but vanishes below the temperature of the carbon arc, and the latter thus does not show any more the unidirectional conductivity of the arc stream to any marked extent. It is therefore an exception, and is not a typical arc.

As in arc conduction the conductor is the unidirectionally moving electrode vapour stream, this stream has first to be produced, by the expenditure of energy, before arc conduction can begin. In an alternating current arc at every half wave a new arc stream has to be started, in opposite direction from that of the preceding half wave of current, and the supply voltage thus must be high enough to jump a static spark across the arc terminals through the residual hot vapour of the preceding half wave. This voltage is low with the carbon arc, but becomes very high with a lower temperature arc.

Entirely different from arc conduction apparently is the conduction of the Geissler tube and of the electrostatic spark. Geissler tube conduction and the electrostatic spark, however, apparently are the same phenomena, differing only by the difference of gas pressure. Thus we can pass gradually from the noisy and brilliant short-circuiting spark to the streamer, brush discharge, corona and to the silent discharge or steady glow. But while a gradual transition from Geissler tube conduction to spark conduction exists, I have never been able to get any gradual transition from Geissler tube conduction to arc conduction. Under conditions where both can occur, the one always changes abruptly into the other, and these two classes of conduction thus seem to be different in their nature: the one conduction by the gas in the space between the electrodes, the other conduction by a stream of electrode vapour. Thus, if we have a Geissler discharge through mercury vapour, of limited current and high voltage, and gradually cut the resistance or reactance out of the circuit, or increase the supply voltage, the Geissler discharge suddenly, with a "flash" changes to arc conduction; the current rises and the voltage drops. Cutting resistance in again, just as suddenly the arc drops, and is superseded by the Geissler discharge. Here, then, we have an very interesting and very important field, in the conduction of gases and vapours, in which still very much is unknown.

"Permanent magnetism" is still an unexplained and mysterious phenomenon. The question is, What is permanent in the permanent magnet? The magnetic flux, or the magnetomotive force, or the flux density or flux distribution, or the magnetic energy?

Another interesting and important phenomenon of magnetism is the loss of energy by a cyclic change of magnetism, as occurs in an alternating magnetic field. Twenty years ago I found this loss to be expressed empirically by the 1·6th power of the magnetic flux density, with sufficient approximation over a wide range of magnetic densities. Since that time, some observers have found that for very high magnetic densities the loss is less than that given by this law of the 1·6th, and other observers find that it is more. Considering the great difficulty of getting exact results at high densities, it appears probable herefrom that even at high densities the law of the 1·6th power still applies at least approximately. For very low densities I have shown that it finally cannot continue to hold, but the coefficient must increase to 2·0. However, with all the work done on magnetism, we still are entirely in the dark regarding the cause of this strange coefficient 1·6. The only other instance of such a fractional exponent is the exponent of the adiabatic expansion curve of gases, 1·4.

Only recently another instance has been found, where the coefficient 1·6 appears. The resistance of pure metals, as the tungsten filament, is proportional to the absolute temperature: $r=aT$. The black-body radiation, however, is proportional to the fourth power of the absolute temperature, and if no other loss of power occurs, as when the radiator is enclosed in a high vacuum, as in the tungsten filament incandescent lamp, the power input equals the radiation power, and thus also is proportional to the fourth power of the absolute temperature, $p=bT^4$. Substituting $r=e/i$ and $p=ei$, and eliminating T, gives $e=ci^{1·6}$.

That is, in a perfect metal, which gives black-body radiation, in a high vacuum at high temperatures the impressed voltage varies with the 1·6th power of the current. This is the only other instance of a 1·6th power law which I found. It may be a mere coincidence, but it is interesting to reflect that here as well as in the hysteresis law, a conversion of electric energy into heat takes place.

Even in fields where very much is known, there are numerous trails leading into unexplored regions. Magnetism, for instance, is one of the most explored branches of electrical science. It was known many years ago that manganese has some curious magnetic properties: a few per cent. added to iron makes it practically non-magnetic. However, it is non-magnetic only in its virgin state, and by heat treatment it is brought into a magnetic state, where it has about the same characteristics as other steels. Here, then, you find a material which may be magnetic or unmagnetic. This trail was never followed up until a few years ago, when a strongly magnetic alloy of manganese, copper and aluminium was discovered. It seemed to overthrow all our conceptions on the nature of magnetism as an elementary property. Even then, however, most investigators followed the same trail, making various alloys of these three metals, and speculating on the cause of the magnetic property of the alloy of three unmagnetic metals, without following the trail further, to the study of other alloys of these metals. Such study shows that copper and aluminium are immaterial for the magnetic property, but that manganese is essential, and is indeed a magnetic metal. Pure manganese has never been produced in the magnetic state, but numerous alloys of manganese, as those with antimony, tin, zinc, &c., are magnetic or may be brought to a magnetic state. Most interesting is the manganese-antimony alloy, as it can be produced much easier than the Heussler alloy of manganese, copper and aluminium. Mixing coarsely powdered manganese and antimony, in the proportion, for instance, of 1 : 3, by moderate heating—in a test-tube over the bunsen burner—the mass becomes strongly magnetic and can be used to show the lines of force of a magnet, just like iron filings. When I tried the magnetic properties of a collection of various alloys, which I had for a considerable number of years, I found quite a number of manganese alloys which showed magnetic properties. Thus after all we do not have to change our conception of magnetisibility as a property of the element, but it merely means that manganese—and possibly chromium—have to be added to the list of magnetic metals.

Oxygen also is magnetic, and now should be easily available, but I do not know that its magnetic characteristics have ever been investigated, except very roughly and qualitatively. While it may not be of industrial importance, it certainly is of great scientific interest, as the only magnetic non-metal and non-conductor. We do not know its magnetisation curve, whether magnetic saturation occurs, and what the saturation value is, whether there is a hysteresis loss, &c., whether and how far ozone shows the magnetic properties, &c.

A curious oxide of chromium has been mentioned for years which has strongly magnetic properties. It is formed by the reduction of chromylchlorid, within narrow temperature limits.

With manganese, a lower oxide of the metal seems to exist, which has much greater magnetic properties than any of the manganese alloys investigated, and even on the old and well-known magnetic oxide of iron, the only data which we have are investigations made 20 years ago, but which apparently have never been continued further.

You see, there is really no lack of unexplored phenomena in the realm of electrical science and engineering. But the two vast fields in which an increased knowledge is of immediate industrial importance, and in which indeed energetic investigating work is going on, are the study of the properties of materials beyond the elastic limit and the study of transient phenomena resulting from the readjustment of the stored energy of systems.

Most investigations of physicists have dealt with the properties of materials below the elastic limit, where the processes are reversible. But of almost greater interest is the range beyond the elastic limit, where the action of forces is not reversible, where mechanically the materials are deformed, such as where steel is rolled into rails, or wire is drawn. So with the electrical forces, in the electrostatic field, irreversible phenomena occur at high voltage, in the corona; energy is stored into the dielectric field, but is not returned, but dissipated as heat, if the dielectric flux density reaches beyond the disruptive strength of the material, and in our modern high voltage transmission lines we have closely approached this limit. In the field of magnetism, the phenomena of hysteresis represent such an irreversible process. So also the ageing of many kinds of magnetic materials, &c.

The second important field of investigation is the study of the transients. Transients are the phenomena by which stored energy adjusts itself to changed conditions of the system. Most of our electrical engineering theory deals with the steady flow of electric power, by direct or by alternating current. But accompanying the flow of electric power is a storage of electric energy in the magnetic and in the dielectric field of the conductor, and any change of the circuit conditions, any change of current and of voltage, thus usually involves a change of the stored magnetic and dielectric energy. Since a change of stored energy cannot occur instantly—as this would represent infinite power—a transition period thus must intervene after every change of circuit condition, that is, an electrical transient occurs. When the electric systems were small, these transients usually were of negliglible energy; but with our modern huge systems, the stored energy is such that the transients frequently may reach destructive powers, and therefore their study has become of great industrial importance.

SOME ALLOYS FOR PERMANENT MAGNETS.*

BY C. F. BURGESS AND J. ASTON.

In the investigation of electrolytic iron and its alloys, carried out at the University of Wisconsin, under agrant from the Carnegie Institution at Washington, tests were made of the magnetic qualities of all samples. Among these, many showed low permeabilities and high coercive forces suggesting their utility for permanent magnets, rather than as electromagnetic material. Upwards of 100 samples were tested for this feature; all the bars contained chromium, manganese, molybdenum, nickel and tungsten as binary alloys, or in various combinations together or with other elements. Much information regarding the best steels and the best treatment for permanent magnets has undoubtedly been accumulated by the manufacturers and users of such material, but is held as a trade secret; and published data along these lines is very meagre. Again, such publications deal largely with the study of the critical points of the steels, with the view to determining the proper heat treatment to give them for the best service.

The tests here recorded are for the most part on carbon free alloys. The results are mainly of value, therefore, as indicating the influence of the various elements in inducing the conditions necessary for a good permanent magnet. They were made upon an Esterline permeameter, an apparatus giving directly the flux density in the bar under test for any impressed magnetising force. It consists of a small dynamo, driven at predetermined constant speed. The test bar forms part of the magnetic circuit of the generator, and can be subjected to magnetising forces of varying degrees. The flux density in the bar, being directly proportional to the voltage set up, can be read off on a properly calibrated millivoltmeter.

It is not necessary to make a complete magnetisation curve in testing material for permanent magnets. The desirable feature is to have as high a residual magnetism as possible, or, better, to have a high retentivity after some disturbing factor has tended to destroy the residual magnetism, together with a high coercive force to resist the tendency towards this loss of the magnetic flux. The method of procedure was as follows: The bar was inserted in the permeameter, the magnetising force H was raised to the maximum of 200 and the density $B_{max.}$ was recorded, H was decreased to zero, and the retentivity $B_{ret.}$ noted; next the coercive force H_c, necessary to reduce the retentivity to zero, was determined. Similar readings were taken for the reverse magnetising forces, and the average of these positive and negative readings of $B_{max.}$, $B_{ret.}$ and H_c for each bar was recorded for comparison. In fact, the whole operation is identical with the taking of a hysteresis loop, in which only the few readings noted above were recorded.

The bars were tested as forged, and after water quenching at 1,000°C. To prevent oxidation of the samples while heating them for quenching, a barium chloride bath was used. The quenching at 1,000°C. may not have brought out the best qualities of some of the bars; but it was deemed the best general treatment, since with so many bars under test it was impossible in this research to subject each sample to tests for its critical points and special conditions of heating.

In addition to the general test noted above, all bars which showed fair retentivity and a coercive force above $H_c=30$ were subjected to a test for their stability or their ability to hold residual magnetism after shock. For this test the bar was subjected to the maximum magnetising force of $H_c=200$, and the retentivity noted when this magnetising force was reduced to zero. The bar was then removed from the machine, subjected to the disturbing factor, and the retentivity again recorded after reinserting the sample in the permeameter. The two means commonly employed in practice for seasoning permanent magnets were used—namely, jarring or rapping the bar, and boiling. For the latter treatment, each bar was inserted in a piece of wrought-iron pipe, which served as a shield to prevent the mutual influences of the magnetic fields, and boiled in water for three hours.

A large number of comparative trials of the rapping and boiling treatments showed them to be practically equal in their effect, and because of the simplicity of the former, it has been resorted to in the later tests. However, should the material be very brittle, it would be safer in practice to use the boiling method.

The alloys tested are divided into five groups, according to their content of chromium, manganese, molybdenum, nickel and tungsten, either alone with iron, or together with iron and any other elements except the above five; in addition, a sixth miscellaneous group includes materials of various compositions in which more than one of the above five metals are present. The results as a whole showed a wide variation in the physical and magnetic hardness of the various bars, not only before quenching, but afterwards as well. Also, it appeared that the effect of quenching was varied in its results, with either increase or decrease of coercive force, or with no material alteration. However, it appeared that where marked changes were the result, it was generally with an increase of magnetic hardness.

Chromium.—In the chromium group, it appears that this element alone, even in percentages as high as 16·65, does not result in bars of high coercive force suitable for permanent magnets, even after quenching at 900°C. And the coercive force was no higher with large than with small chromium additions. A large number of chrome-silicon alloys were tested, and in practically all cases the bars were relatively soft and of low coercive force in the forged condition. The coercive forces in all but two instances were well below 30, and the alloys were thus unsuited in this state for permanent magnets. In these two instances but little change resulted on quenching; but for the other bars, quenching resulted in a marked increase of coercive force; and with the accompanying relatively high retentivities, these materials were well adapted for permanent magnets. The best alloys seemed to have about a medium chromium content (5 or 6 per cent.), since then the retentivity was high and the coercive force great enough to ensure stability.

The addition of vanadium also seemed to be very beneficial, although in this case the raw forged bars were especially hard, and the coercive forces were high initially, and suffered but little change in quenching. Here, again, the best results seem to be gained with medium chromium content, because of the higher retentivities. In a few instances, carbon was present, together with vanadium and silicon. The materials showed hardening upon quenching, but the magnetic results were no better than where there was no carbon.

Summarising, it may be said that the addition of chromium alone to carbonless iron will not result in a material suitable for permanent magnets; but that the further addition of 0·75 to 1 per cent. of silicon or 0·3 to 0·5 per cent. of carbon to 5 or 6 per cent. of chromium is highly beneficial, and gives an alloy very suitable for this class of service.

Manganese.—According to the classification adopted, the only manganese alloys falling in this group were of a series in which manganese alone in varying amounts had been added to the iron. In the raw forged condition, the coercive force increased, with a corresponding decrease of retentivity, for each increase of manganese content, until at 10·41 per cent. Mn the alloy was non-magnetic. A bar with 10 per cent. of manganese had the high coercive force of 90·1, but the retentivity was too low for permanent magnets. The most satisfactory bars were two with 4·51 and 6·0 Mn, where the retentivities were fairly high and the coercive forces great enough to ensure stability. But three bars were tested after quenching, and the result was a decrease of coercive force, a peculiarity corroborated by other tests upon this series.

Molybdenum.—Of the entire set of this series of alloys, only one was magnetically hard in the forged condition; this was a bar of composition 8Mo, 0·3V, 0·6C, which had the high retentivity of 9,200 and the fair coercive force of 39·0. In the quenched condition, there was practically no change in any of the carbon free alloys. But in four cases where carbon was present the quenching resulted in physical hardening of the bars, and they became very fine materials for permanent magnets, with exceptionally high retentivities and very good coercive forces. In one case, a bar with 4Mo and 0·6V attained a good coercive force; whether this was due to absorbed carbon is problematical. If the magnetic hardening took place without the aid of carbon, it would indicate that the proper conditions of temperature, &c., might have the same effect on the other molybdenum alloys. This is merely conjecture, however, and the tabulated results showed no hardening effect of vanadium, such as was noted for the chromium alloys.

Nickel.—In the binary alloys of nickel and iron, increase of nickel caused a decrease of retentivity and increase of coercive force, until at about 26 per cent. of nickel the material was non-magnetic. Beyond this percentage, the magnetic properties were restored, the alloys being of rather high permeability and low coercive force. Quenching at 900°C. invariably greatly decreased the coercive forces, so that none of the binary nickel alloys can be considered suitable for permanent magnets in the quenched condition, either because of low coercive force or because of low retentivity where the coercive force is ample. The addition of vanadium resulted in increased magnetic hardness, which was again increased by quenching. The most satisfactory bar was one with 10Ni and 0·6V, which in the forged condition had a retentivity of 9,900 and a coercive force of 32·6; both values were slightly lowered by quenching. One bar with 10Ni, 2Si, 1C had a fair retentivity of 6,800 with a high coercive force of 62·0 in the forged condition; but after quenching it became almost non-magnetic. The nickel alloys as a whole, therefore, cannot be regarded as satisfactory materials for permanent magnets. In this case, as noted for chromium, the vanadium seems to act as a hardening agent.

Tungsten.—Seven binary alloys of tungsten and iron were recorded, with a tungsten content varying from 0·93 to 23·87 per cent. In no

* Abstract of a Paper read before the American Electrochemical Society.

Digitized by Google

instance was the coercive force high enough to make them suitable for permanent magnets; and quenching had but little effect, usually resulting in a decrease of coercive force. For the two alloys, where there was an addition of vanadium, one bar, with 4W and 0·4V, became, after quenching, an exceptionally good permanent magnet, with a retentivity of 11,300 and coercive force of 43·8; on the other hand, another sample, with 7W and 0·3V, experienced but slight increase of hardness. A bar with 5W and 0·5C became noticeably harder after quenching, with increase of retentivity and coercive force to the high values of 11,700 and 59·0. Four other bars were good for permanent magnets as forged, and there was a marked hardening due to quenching. Summarising, the binary alloys of tungsten and iron are not satisfactory for permanent magnets. The addition of vanadium may be beneficial, and the addition of carbon certainly is. There were in this series some highly satisfactory alloys; of those worthy of particular mention, however, all but one contained carbon.

Miscellaneous.—This miscellaneous group included such a large number of combinations of these several self-hardening alloys that a systematic discussion of the results is difficult. Of the 51 bars here grouped, almost two-thirds were good materials for permanent magnets. The effect of quenching was somewhat varied; in 13 instances there was a considerable increase of coercive force, in 30 cases but little change, and in six instances a marked decrease. In four cases bars which were originally poor became of fair quality after quenching; and in numerous instances the quality of fair materials was greatly improved; in no case, however, has quenching resulted in a bar of fair quality becoming poor material for permanent magnets although at times the quality was better before quenching than after. One of the most striking features noted was the detrimental effect of the additions of nickel, with its tendency towards non-magnetic alloys. In all cases where the material was classed as non-magnetic, or where it was worthless for permanent magnets because of very low retentivity, there was a considerable amount of nickel present. Of the 17 bars of poor quality for permanent magnets, 12 had nickel; and of the five bars without nickel, the quality was poor not because of a tendency towards being non-magnetic, but because the coercive force was too low. Several bars of nickel with chromium, with molybdenum or with tungsten, had fair retentivities together with high coercive forces. The various combinations of chromium with molybdenum or tungsten, either alone or with additions of silicon, vanadium and carbon, gave generally satisfactory results. In fact, it is difficult to point out any preferable combinations of these various self-hardening elements beyond the caution to keep nickel out of the alloy. Of particular quality may be mentioned the following:—

Bar.	Composition.	$B_{ret.}$	H_c	
136M	5Cr 3Mn 4Mo 1St	11,350	55·8	As forged
136V	10Ni 5Mo	10,150	36·7	,,
150C	2Cr 10Mo 0·5C 0·3V	10,500	78·0	Quenched
155Y	10Ni 5W	10,300	35·2	,,
156A	1Mn 2Mo	10,500	39·6	,,
155P	1Mn 10Mo 0·5C.	10,750	58·4	,,

Strange to say, two of these alloys have a high nickel content, but they may be put down as exceptions to the general rule. The values given above indicate a very high standard of material for permanent magnets.

Summarising, it may be deduced from the above tests that chromium, manganese, molybdenum and tungsten are the important additions in the manufacture of steels for permanent magnets; but the presence of some third element is necessary. While carbon is beneficial, it is possible to obtain highly satisfactory materials either by various combinations of the above four elements or by suitable additions of silicon or vanadium, the latter, in particular, being very desirable. Also, suitable materials may be made which will require quenching, although in this case carbon is most beneficial; or, if desired, equally satisfactory results may be obtained without.

Stability.—As mentioned previously in the general discussion of the tests for permanent magnets, a better indication of the value of material for this service is obtained by a stability test which gives the residual magnetism after shock. In our tests the rapping method was used, the details being given above. Those bars were tested which showed a coercive force above 30, either before or after quenching, this being considered the minimum value at which permanence might be expected. The figures of interest are those for the retentivity $B_{ret.}$ after rapping; they show the marked decrease of the residual magnetism due to shock, a decrease averaging about 50 per cent., but varying according to the coercive force of the material under test. As a result of these tests, it appears that for the investigation of materials for permanent magnets, this stability test gives a very satisfactory indication of the quality. In addition, of course, it would be necessary to test the ageing qualities, or the ability to retain this residual magnetism for long periods of time, and under working conditions.

VARIATION OF THE RESISTANCE OF SELENIUM WITH THE E.M.F.*

BY J. LUTERBACHER.

W. G. Adams found during his experiments on crystalline selenium that the resistance of a selenium "cell" varies with the E.M.F. to which it is exposed, and that, in general, the resistance decreases as the E.M.F. increases. This effect is examined in detail in the present Paper, with a special consideration of the alternate-current resistance.

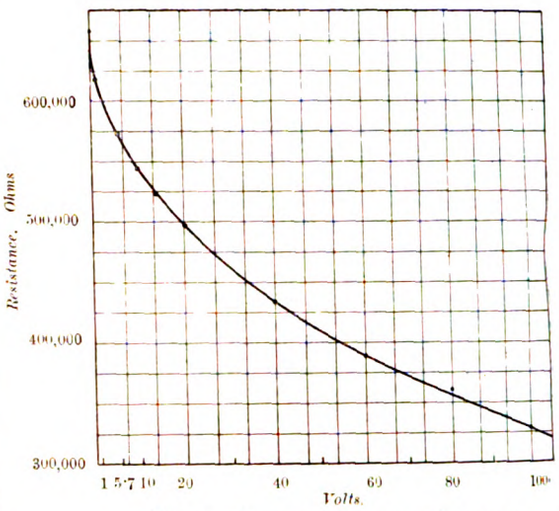

FIG. 1.—VOLTAGE EFFECT IN SELENIUM.

In all the tests the variations due to illuminations and heating were eliminated by keeping the cells for several days together at a temperature of melting ice and in absolute darkness.

Most of the cells examined were of the Shelford–Bidwell pattern. To these was added a Ruhmer cell of the glow-lamp type.

The cooling was carried out by enclosing the cells in a water-tight brass box containing a piece of calcium chloride for absorbing traces of moisture. The box was then surrounded by 10 kg. of ice in small pieces, which was renewed as found necessary.

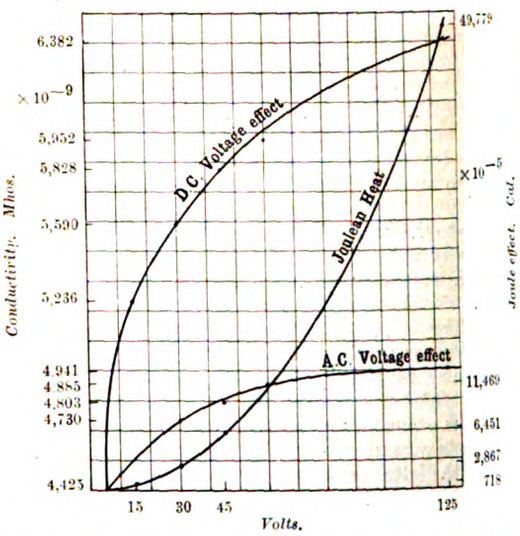

FIG. 2.—VOLTAGE EFFECT COMPARED WITH JOULEAN HEAT.

The following questions were investigated:

1. Is the resistance as measured with a small E.M.F. permanently affected by a high E.M.F., or only temporarily?
2. Has the effect the same direction in all cells, and is it proportional to the E.M.F.?
3. Is the effect the same for direct currents as for alternating currents?
4. Is the photoelectric sensitiveness of the cells affected by treatment with high E.M.F.s?
5. Is the decrease of resistance due to the heating of the cell?

* Abstract of an article in the "Annalen der Physik."

Digitized by Google

The author calls the effect studied the "voltage effect" or "tension effect" (*Spannungseffekt*). It had the same sense—that of an increase of conductivity with rising E.M.F.—in all cells except one, which showed an inversion.

The voltage effect is greater with direct currents than with alternating currents. There is in general no proportionality between the applied voltage and the voltage effect, a given difference in voltage being less effective at high voltages. The voltage effect is not instantaneous, nor does it disappear at once after taking off the high E.M.F. The time of recovery increases in general with the voltage and the time during which it was applied. The photoelectric sensitiveness is not affected in any way by the voltage effect. The latter may be connected with a polarisation in the direction of the current. It is not at all explained by the heating effect due to the current.

The above are the main conclusions arrived at by the author. A number of interesting details are given.

The Ruhmer cell was studied with direct currents from a battery of accumulators, the voltage ranging from 0·1 volt to 100 volts.

The following table and the curve in Fig. 1 give the results :—

E.M.F. volts.	Resistance, ohms.	Period of recovery, minutes.
0·1	658,200	
1	617,400	20
5·7	573,500	20
10	544,200	25
20	498,200	20
40	435,400	60
60	389,200	35
80	361,700	30
100	329,800	35

The curve is approximately a parabola. It differs from the photoelectric curve in not commencing as steeply as the latter.

The light effect was studied both before and after these experiments, and showed no difference attributable to the voltage effect.

All the Gilthay cells showed a gradual rise of resistance in the dark. In one of them this gradual rise continued for a month, during which the resistance rose from 135,400 to 228,000 ohms. This cell showed a sudden recovery after direct voltages up to 30, but not for stronger direct currents, nor for alternating currents.

Another Shelford-Bidwell cell showed a curious anomaly in the voltage effect in the shape of a minimum resistance under 5 volts, with a gentle rise towards 100 volts.

That the Joulean heating is not the cause of the voltage effect is shown by the aspect of the curves (*see* Fig. 2) which show that the Joule effect increases very slowly at low voltages, whereas the voltage effect rises abruptly, even for alternating currents. Besides, if the Joule effect were the cause, there is no explanation for the difference between the direct current and alternating curves.

On cutting off the voltage abruptly and leaving the selenium cells discharge through a galvanometer, polarisations of 7 to 22 millivolts were observed for a few seconds. The author suggests that this polarisation stays in the same direction as the original current) may be much stronger when the current is on, and may thus explain the voltage effect.

Electricity in a Lumber Mill.—The "Electrical Review and Western Electrician" gives an account of an electric-driven lumber mill at Brooklyn, U.S.A. A special feature is the use of band saws for nearly every cutting operation, and each machine throughout the entire mill is driven by an individual motor. These motors are of the squirrel-cage type and aggregate 950 H.P. During the past month the company has also started in operation a sash and door factory equipped with 45 machines, each one driven by its own individual motor. These motors are the same as in the mill, and aggregate 300 H.P.

DUBILIER WIRELESS TELEGRAPH STATION AT SEATTLE.

A wireless telegraph station has recently been erected by Mr. W. Dubilier on Puget Sound, near Seattle, U.S.A., and as the equipment is very complete the following details, which

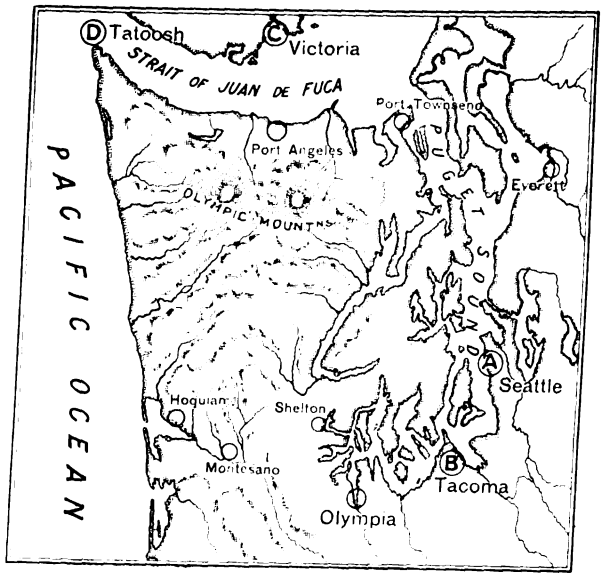

FIG. 1.

have been placed at our disposal, will no doubt prove interesting to our readers. As the station was to have a world-wide range, many points had to be considered in its construction, such as high mast, large surface area, high altitude, and a position near a satisfactory body of water. Many locations on Puget Sound were investigated before an ideal spot was

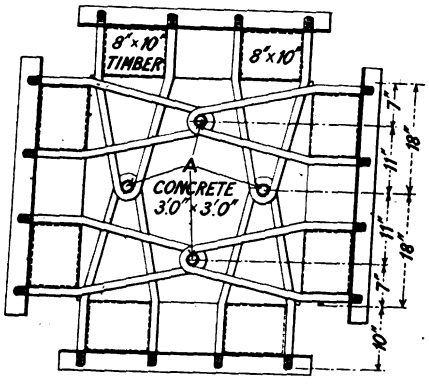

FIG. 2.

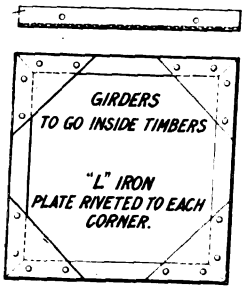

FIG. 3.

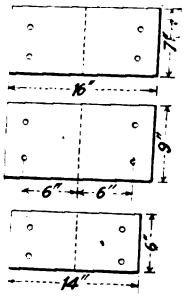

FIG. 4.

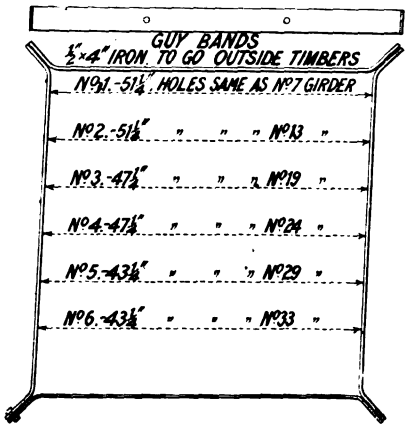

FIG. 5.

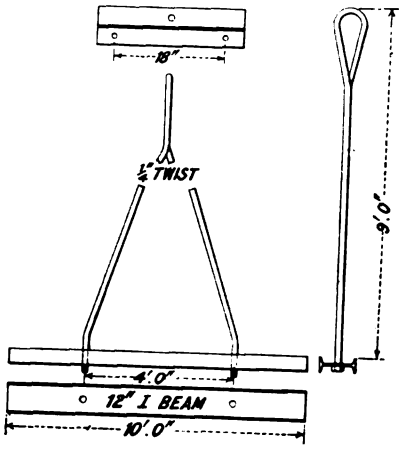

FIG. 6.

finally found near Fauntleroy Park, approximately 3 miles from Seattle, 500 ft. above the sea level, on a sharp bluff dropping into Puget Sound. A in Fig. 1 shows the position with reference to Puget Sound, whilst B, C and D show Tacoma, Victoria and Tatoosh, all of which reported that they heard the wireless telephone from Mr. Dubilier's laboratory. The Tatoosh station, which is about 140 miles over the Olympic Mountains, finds it impossible with 25 H.P. to communicate with the Bremerton Navy yard near Seattle in the daytime and very difficult at night; daily wireless telephonic communication, however, is commercially held between A and B (Fig. 1).

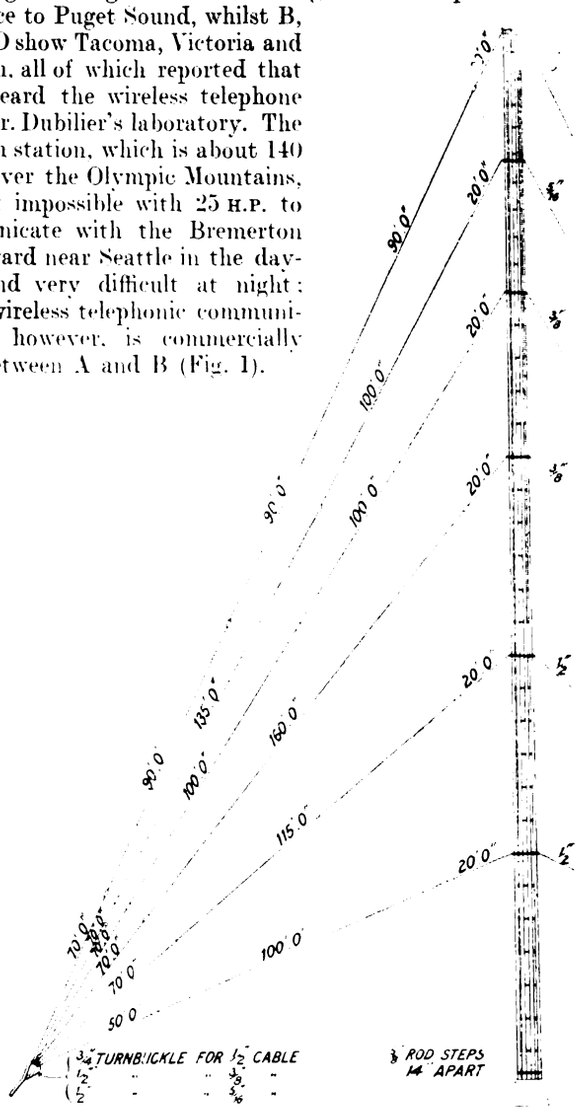

FIG. 7.

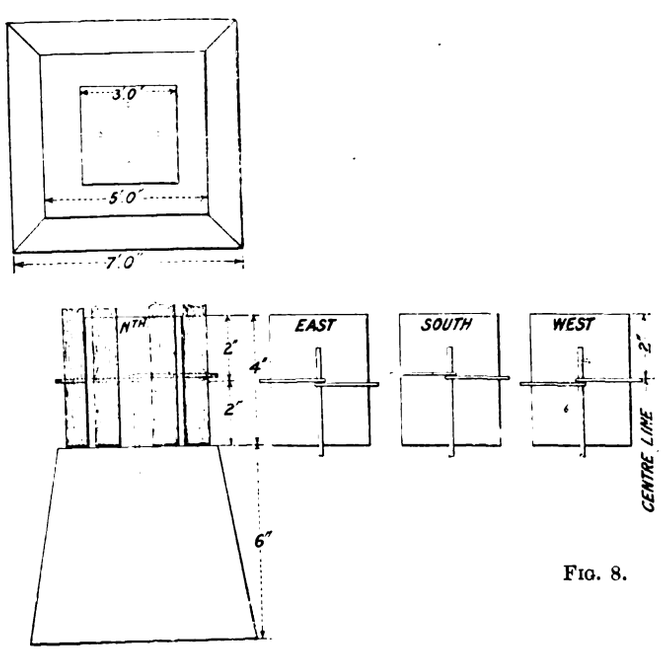

FIG. 8.

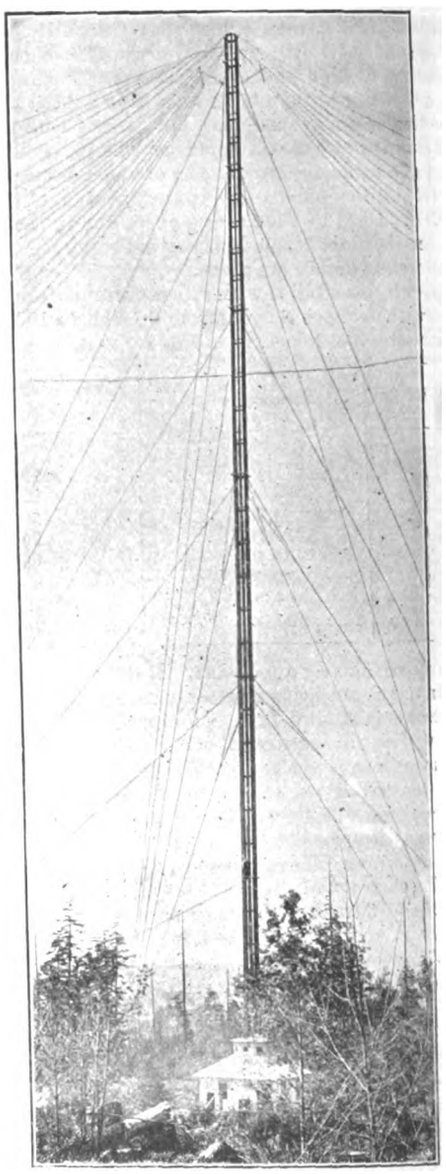

FIG. 9.—AERIAL WIRE SYSTEM AND TOWER OF EXPERIMENTAL STATION AT SEATTLE.

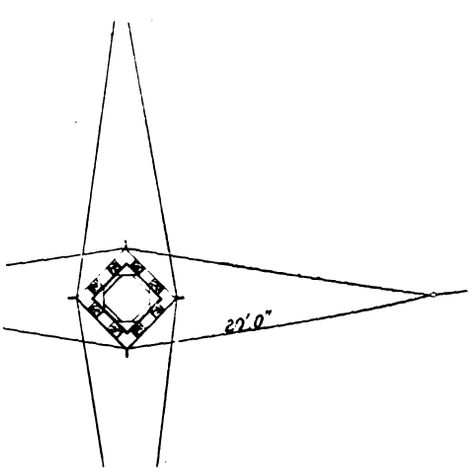

After considering and experimenting with the different forms of aerials, it was decided to adopt the umbrella type, which was found most suited to overcome the surrounding conditions, for mountains arise in nearly all directions to a height of 5,000 ft. or more. The Sound, which varies in width up to 2 miles, is the only water outlet, as will be seen in Fig. 1.

The tower measures 320 ft. from the base, giving it a total height of 820 ft. above sea level; and, to make room for the aerial wire system, 30 acres of high timber had to be cleared.

Digitized by Google

Numerous springs exist on the hill, and so it was possible to obtain a permanently damp ground.

Erection of Tower.—Many original ideas were embodied in the design of this mast to withstand the high winds which occur during the winter season. It was necessary to make the mast as flexible as possible and at the same time of the necessary strength.

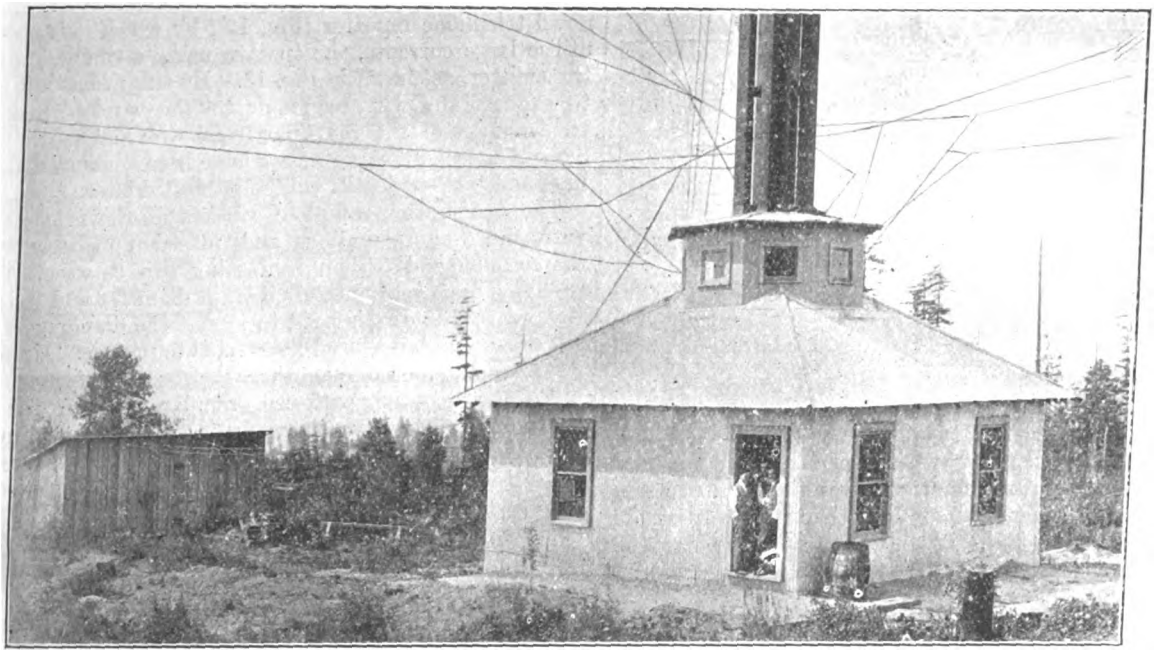

FIG. 10.—VIEW OF OPERATING ROOM, ENGINE ROOM AND BASE OF TOWER.

To support the wooden structure a solid concrete base was imbedded in the ground to a depth of 8 ft., each side measuring 7 ft. at the base and 5 ft. at the top, the total height being 6 ft. Four reinforced steel rods 1¼ in. in diameter were imbedded in the concrete, as shown at A in Fig. 2, which were used for the large bands to hold the base beams, as will be noticed from the illustration. Eight beams were used, two being on each side

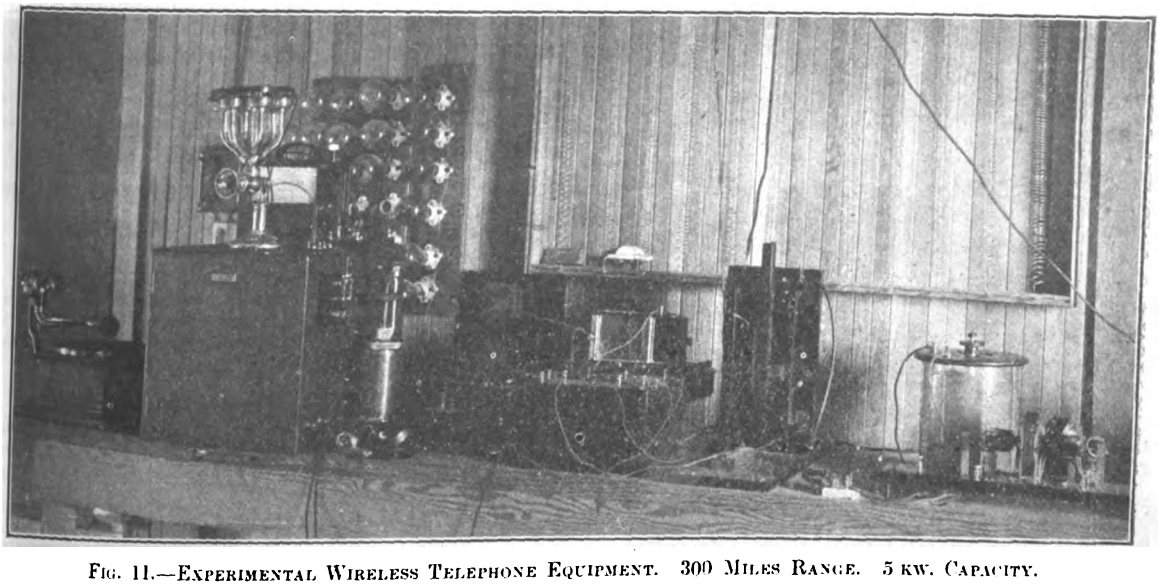

FIG. 11.—EXPERIMENTAL WIRELESS TELEPHONE EQUIPMENT. 300 MILES RANGE. 5 KW. CAPACITY.

the square and bolted to the reinforced rods. These varied length, the first being 8 in. by 10 in. by 5 ft. high, the next ft. high, the next 15 ft. high, &c., each one increasing by ft. up to 40 ft. Thereafter all the beams were made 40 ft. gh, so that the same ratio for interlapping remained all the ay to the top, no two joints being in the same place.

I beams and girders were used to hold the masts together. g. 3 shows the girders reinforced by angle plates, which hold the timbers together from the inside and which were placed every 10 ft. Fig. 5 shows the bands bolted on the outside of the timbers and used for the guys, these being placed 80 ft., 70 ft., 60 ft., 50 ft. and 40 ft. respectively from the base.

For hoisting the timbers, each successive timber was used for a gin pole, and by means of a small engine hoist the work was done very cheaply and quickly. The beams were connected to each other by ⅝ in. iron plates and ⅝ in. bolts, as shown in Fig. 4. The anchors for the guys were made of 12 in. I beams 10 ft. long, and buried 10 ft. deep in the centre of concrete. Through the I beams steel rods are twisted as shown in Fig. 6 and bolted, to which the guy wires are clamped. The guy wires are broken at intervals with strain insulators, and vary from 1 in. in diameter at the bottom to ½ in. at the top, making six sets in all; and for each set four were used at right angles to each other. To prevent the twisting of the tower, they were connected to the steel bands, as shown in Fig. 8. Fig. 7 shows the complete tower with guys, a view being given in Fig. 9.

The Aerial Wire System.—The aerial wire system is of the umbrella type, and is divided in eight sections, each section containing eight wires and running out to smaller poles 120 ft.

Digitized by Google

high and 500 ft. from the base of the tower, in all containing about 40,000 ft. of stranded phosphor-bronze aerial wire, so connected that each section or any number may be used at a time.

Operating Room.—Fig. 10 shows the operating room at the base of the tower, the noise of the independent power plant, seen at the left, being excluded. The building is divided into

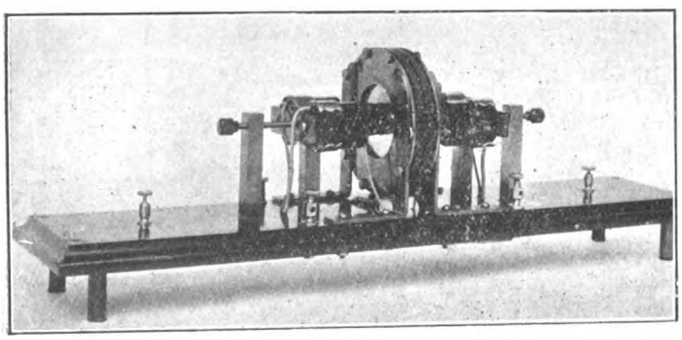

FIG. 12.—TELEPHONE REPEATER USED AS TRANSMITTER.

two sections, one for telegraph work and the other for telephone experiments. The telephone experimental room is shown in Fig. 11, and consists of a complete transmitting and receiving outfit, using the "quenched arc" method. It was decided to name this the "quenched arc," for it is neither a quenched spark nor an oscillation arc, whilst partaking of the nature of both.

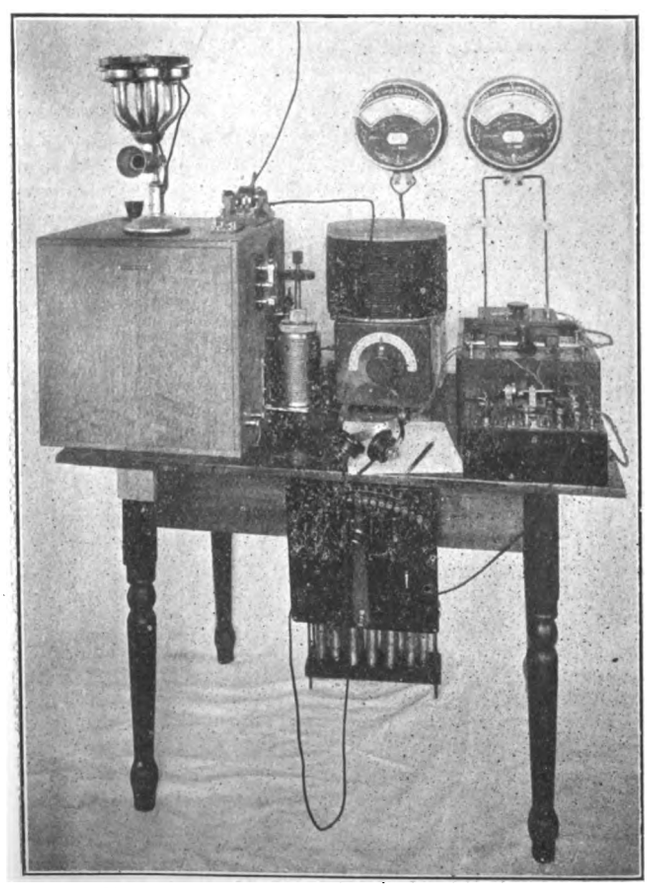

FIG. 13.—COMPLETE STATION, DUBILIER SYSTEM.

The transmitter consists of a newly-designed oscillator. Condensers and tuning coils all meet in the box of the transmitter, shown in Fig. 11. A double-pole double-throw switch is used for making the system direct or loose coupling, and a small aerial switch on top of the box for changing from transmitting to receiving. By means of another switch on top it is possible to use the same transmitter with the addition of a rotary gap as a musical note wireless telegraph system, any note being obtained by simply varying the speed of the motor running the interrupter.

Different telephone transmitters are being experimented with, good results having been obtained with six of the Berliner type connected in parallel and mounted on top of the box (Fig. 11). In the most recent experiments, however, the inventor, in conjunction with Mr. V. Laughter, has evolved a novel telephone repeater (Fig. 12), by which it is possible to utilise large currents, the speaker using a simple low-current transmitter, as shown in Fig. 13. By this means it is possible to connect the wire telephone to the wireless, making the transmission of the voice partly by wire and partly wireless. Several successful experiments have been conducted along this line, and further details will be published later.

The transmitter complete consists of the magnets wound with the 2-ohm windings and placed oppositely with the diaphragms and carbon containing cup between. The diaphragms are approximately 5 in. in diameter and $\frac{1}{28}$ in. thick. A hard rubber disc is used to mount the diaphragms on, and is drilled with large-sized holes so as to prevent "air packing" or talking against one another.

To make contact with the granular mass, circular rings of platinum are used, which are first soldered to the diaphragms. The platinum rings are drilled with small holes around the entire circumference so as to allow a free circulation of air, and through one of these holes the small inlet and outlet tubes are run, the contact being made in the centre of the granular mass. A mica disc is used to retain the granules in the chamber.*

At present 35 H.P. is available, which will be made use of for the telegraph to communicate with a similar station in Alaska.

The receiving apparatus consists of the variometer tuning coil, constructed so that the secondary revolves in the centre of the primary. This was found to give more selectivity than any coil yet tried, besides eliminating static interference. A detector box containing four different detectors—perikon, silicon, iron pyrites and galena—is used, and is arranged so that any detector can be used. It was found that good results can be obtained with almost any form of crystal detector, using a battery giving 0·2 volts, the current being in the direction of rectification. A steel needle on carborundum floating in mercury seems to stand up longer under the strain and does not burn out, and from the experiments made it was found that the articulation is far superior with the carborundum detector than with any other.

THE EFFECT OF VARYING PROPORTIONS OF AIR AND STEAM ON A GAS PRODUCER.†

BY E. A. ALLCUT, M.SC.

Summary.—The author's investigations, which were made on a small gas producer, were mainly with the object of determining the effect on its efficiency of varying proportions of steam. His results are compared with those of Bone and Wheeler.

The experiments here recorded were performed on a small gas producer at the University of Birmingham. The chief object of the research was to determine the influence of varying quantities of steam on the general working and efficiency of a producer plant of small size. The supply of air to the producer was, therefore, kept as nearly constant as possible in all the trials, while the steam supply was varied from nothing to a maximum of 1·14 lb. per lb. of coal. Anthracite peas were used throughout the trials. The steam required was generated within the producer, so that the general conditions closely resembled those under which a modern suction plant works; the sole exception being that the air was forced into the ash-pit by a fan. A series of similar trials were performed in 1906 by Messrs. Bone and Wheeler,‡ on a 2,500 H.P. gas plant.

* *See* THE ELECTRICIAN, Dec. 13, 1910, pp. 462-3.

† Abstract of a Paper read before the Institution of Mechanical Engineers.

‡ "Journal," Iron and Steel Institute, 1907, No. 1.

Digitized by Google

The author first discusses the reactions taking place in the producer and shows that the steam supply has an important effect, as it controls the temperature at which the reactions take place, and therefore the composition and yield of gas and the efficiency of the process. If the steam supply is increased above a certain amount per lb. of carbon, the temperature and efficiency of the plant both fall. If, on the contrary, the supply is cut down too low, the temperature rises, gives bad working and increased heat losses, and yields

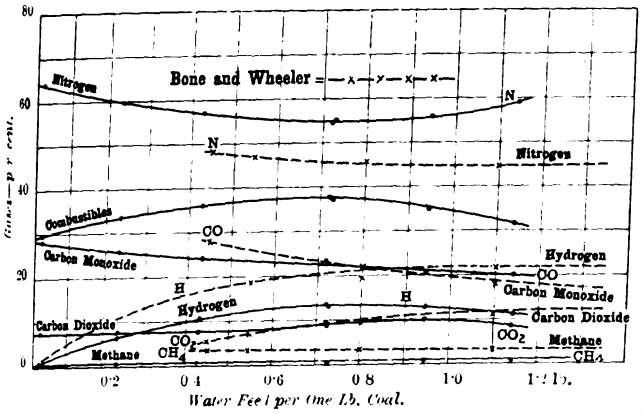

FIG. 1.—GASES. COMPARISON WITH 1906 TESTS.

a poor gas. It was one of the objects of these trials to find the proportion of air and steam that will give maximum efficiency.

A description of the plant, which was made in the workshops of the University of Birmingham, is next given by the author. The washer, Fig. 3, is of novel construction. It consists of a cylindrical shell (18 in. diameter by 48 in. long), closed at the ends, and traversed by a shaft strung with thin discs 17 in. diameter. This shaft is rotated at 76 revs. per min. The discs are alternately pierced at the edge C, and the centre D, so that the gas is forced to pass in a zigzag direction from one end of the washer to the other. The washer is partly filled with water which is picked up by the small vanes on the discs marked C, and dashed intimately into contact with the gas. The large area of wetted surface thus presented to the gas makes this type of washer very efficient as a cooler.

The reason for the adoption of a small plant was to enable it to be tested in a short time. The actual duration of each trial was four hours, but the plant was run for some three or four hours in each case before any readings were taken, to enable the conditions to become steady.

The results of the tests are given in tables and curves. Fig. 1 herewith shows that the percentage of hydrogen in the gas does not increase with increase of water fed into the producer, when the latter

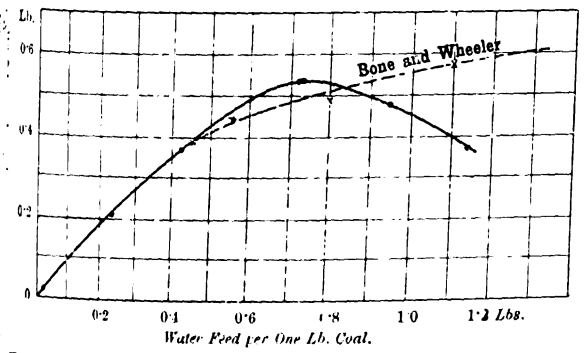

FIG. 2.—WATER DECOMPOSED PER LB. COAL. COMPARISON WITH 1906 TESTS.

exceeds 0·75 lb. per lb. of coal. This corresponds to the decomposition of about 72 per cent. of the total weight of water fed in the producer. This result is very important, as it shows that the maximum amount of steam that can be decomposed by anthracite at a temperature of about 1,832°F. is about 0·535 lb. of coal (Fig. 2). Referring to the curve of Messrs. Bone and Wheeler (shown dotted Fig. 2), it appears from the flattening of the curve that this maximum is in the neighbourhood of 0·625 lb. of water per lb. of coal, for large producers working on bituminous coal. It follows that there can be no advantage, but only loss, in pushing up the steam supply beyond 1½ lb. of steam per lb. of coal for large producers and about ¾ lb. of steam per lb. of coal for small ones. If these values are greatly exceeded, the increased supply of steam merely takes heat from the producer and loses it in the washer. The presence of such excess of steam has, of course, an effect in keeping down the temperature of the producer, and this is advantageous when it is desired to recover ammonia from the gas, but in all other cases such excess is harmful, as it has been repeatedly shown that large quantities of steam are not necessary for the prevention of clinkering. The low percentage of hydrogen in the gas is due to the large quantity of air which had to be used to keep the vaporiser at a sufficiently high temperature to supply the necessary amount of steam, owing to the inefficiency of the internal steam coil.

The most significant result of these trials is that the percentage of CO_2 remains practically constant, in spite of the increasing feed of steam to the fire. The high content of CO_2 in the trials where little or no steam is supplied, is due to a leakage of air through cracks in the lining. Eliminating the 7 per cent. of CO_2 in the first trial as due to this cause, it is found that the maximum rise during the whole of the trials is merely about 2·5 per cent. It would naturally be expected that the increased supply of steam would diminish the temperature inside the producer, and result in the production of increasing quantities of CO_2. This is admirably shown in the trials of Messrs. Bone and Wheeler (the CO_2 is shown dotted, Fig. 1). Why does not the same rise occur in the author's experiments? Readings taken show that the temperature kept fairly constant at about 1,832°F. for a distance of about 18 in. upwards from the grate, and then falls rapidly to about 1,112°F. in the next 6 in. or so. The

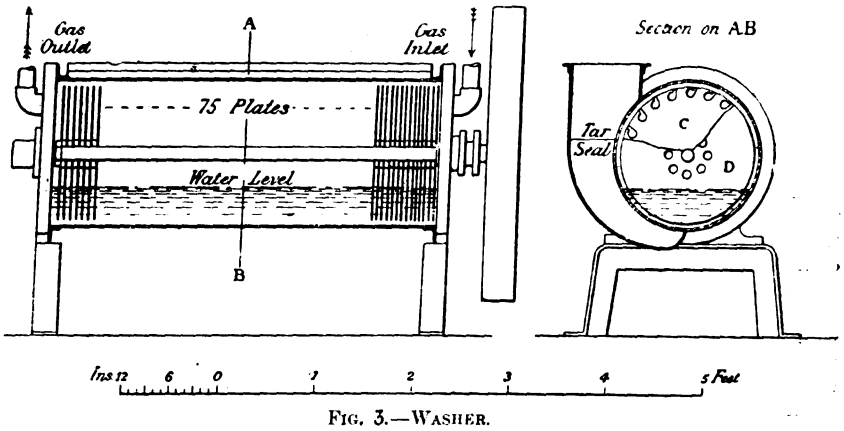

FIG. 3.—WASHER.

first 18 in. may be termed the zone of active combustion, where, owing to the high temperature, the gases produced are almost entirely CO and hydrogen. There is above this about 6 in. or 7 in. of fuel bed in which the temperature is rapidly falling. This would have its due effect in re-forming the CO_2 if it were not so thin. The shallowness of this comparatively cold layer of fuel does not allow sufficient time for these reactions seriously to affect the composition of the gas and the efficiency of the producer.

In a deep fuel bed, say 7 ft. deep, as in the producer used by Messrs. Bone and Wheeler, the first 2 ft. or so will form the zone of active combustion, but the thickness of the bed of cooler fuel above will much more seriously affect the composition of the gas. In fact, the amount of CO_2 in the resulting gas will simply be the result of the reactions corresponding to the mean temperature of the belt above the zone of active combustion, and to the time during which the gases are in contact with the coal in that belt—that is, it will depend upon the depth of fuel in the producer, beyond the zone of active combustion, and the velocity of the gas. This shows that in producers which have a shallow fuel bed, provided there is no leakage, there need not be more than 2 per cent. or 3 per cent. of CO_2 present in the gas. If more than this quantity is present, it is due either to leakage or to the use of too great a quantity of air for the size of the producer. In the latter case, the velocity of air through the fuel is high, and some of the CO_2 formed by combustion in the active zone escapes reduction to CO. The depth of the fuel bed should therefore be cut down to the lowest value consistent with practical working. In large producers a deep fuel bed is necessary, as the larger sizes of coal used in them do not pack as well as the smaller pieces, and the distribution of air across the section of the fuel-mass is apt to be irregular. In such cases it might even pay to have a secondary air supply admitted some distance above the grate. This would have the effect of introducing another zone of active

Digitized by Google

combustion, in which the heat evolved by the combustion of the secondary air to form carbon monoxide, would be available for reducing the CO_2 coming from the grate. The depth of the cool layer of fuel above the active combustion zone would thus be reduced, and the re-formation of CO_2 would be greatly diminished.

The calorific value was found to reach a maximum at 0·7 lb. of water per lb. of coal, and the maximum yield of gas to be at about the same point. The efficiency of the producer (the ratio between the heat generated which does useful work outside the producer itself, and the total heat in the coal used) rose from 48 per cent. with no water to 75 per cent. at 0·75 lb., decreasing again above this point.

The highest temperature of the gas leaving the producer was attained where no water was fed into the vaporiser, being about 750°F. A steady fall was maintained with the increase in water-feed until at about 0·7 lb. water-feed the temperature was about 550°F. After this, the temperature remained fairly constant.

The efficiency was found to be proportional to the ratio (oxygen in steam)/(oxygen in air), up to a ratio of 0·65, after which it bends sharply and becomes inversely proportional to that ratio. The down grade of the curve is almost exactly parallel to the results obtained by Messrs. Bone and Wheeler. It appears from this, that the increased supply of steam beyond the point of maximum efficiency causes a decrease in efficiency proportional to the ratio (oxygen in steam)/(oxygen in air). This decrease, in the case of these two producers, is the same for equal rises in the value of the ratio. Whether this also holds for other producers can only be determined by further investigation, but the fact that it is the same for two producers that are so different as these are appears to be significant.

INVESTIGATION OF THE ELECTRICAL STATE OF THE UPPER ATMOSPHERE.*

BY A. J. MAKOWER, M.A., W. MAKOWER, M.A., D.SC., W. M. GREGORY AND H. ROBINSON.

The present experiments were undertaken during August, 1910, to investigate the electrical state of the air at different heights above the ground by mans of kites and balloons, and form a continuation of those carried out in the two previous summers at Glossop. By the kindness of Mr. C. J. P. Cave, who put his kite station at Ditcham Park, near Petersfield, in Hampshire, at our disposal, we were enabled to make observations above ground which, although somewhat undulating, approximated more nearly to flatness than at the Glossop kite station, situated in the most hilly part of the Peak District.

The method of carrying out experiments was similar to that already described, and consisted in flying a kite or, in calm weather, a balloon attached to a steel wire. For measuring potentials the wire was anchored to long ebonite insulating rods, strong enough to take up the pull exerted, and an electrical connection was made by means of a wire supported by long ebonite insulators and running through glass tubing to one pole of a Kelvin-White high potential electrostatic voltmeter, the other pole of which was connected to earth. The potential taken up by the kite was read directly on the voltmeter. The wire which was used was divided up into a number of sections connected together by spring hooks, so that various lengths could be detached from the winding drum, in order to obtain readings at different heights. The height above the ground was determined by measuring the length of wire let out, and the angle of the kite above the horizon, and also from the readings of a self-recording aneroid barometer sent up with the kite. The potential recorded by the voltmeter was assumed to be that of the air surrounding the kite or balloon. The validity of this assumption has already been discussed, and it seems probable that it is not far from the truth.

After each observation of the potential a measurement was made of the current that flowed down the wire when it was earthed through a suitable galvanometer. On one occasion a high resistance of cadmium iodide dissolved in amyl alcohol was inserted in series with the galvanometer. From the reduction thus produced in the current flowing through the galvanometer, it was possible to form an estimate of the resistance of the air from which the kite was collecting electricity. With the kite at a height of 1,400 ft. it was found that the resistance of the air was of the order 1,000 megohms, a number which confirms the estimate made in a previous Paper. In order to get some indication of any variations of the electrical state of the atmosphere during the ascents, which sometimes lasted several hours, measurements were made of the potential gradient near the ground with a radium collector in the usual manner. Although the observations taken in this way just before and just after an ascent were of use, it was found that readings taken while the kites were in the air were useless, as the potential gradient over the ground was completely changed by the presence of the kite; this was made evident by the fact that the readings obtained for the ground potentials were found to vary considerably when the kite-wire was alternately insulated and earthed.

The results of the experiments are given in curves and tables in the Paper, the potential gradients being much steeper on some days than on others. Furthermore, considerable variations frequently occur on the same day. A typical curve is given in Fig. 1.

With a view to ascertaining the rate at which an ascending or descending balloon acquires the potential of the air surrounding it,

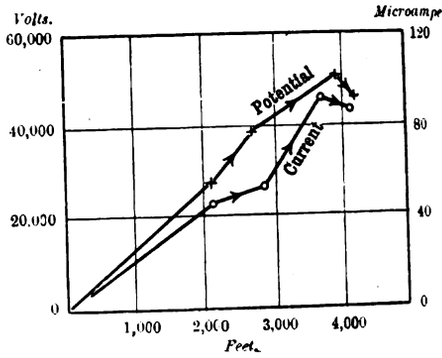

FIG. 1.—AUGUST 12. KITE.

measurements were made of the time taken for the kites or balloons to take up the potential of the air; such observations afford an estimate of the rate of charging up of a balloon suddenly raised to the altitude at which the experiment is being made. The collecting area of the sails of the large kites used by us was about 150 sq. ft. and that of the small kites about 100 sq. ft., reckoning both sides of each sail as available for collecting electricity, and that of the balloon, which was of gold-beater's skin, about 150 sq. ft., so that the collecting areas were small compared with that of a balloon for carrying passengers; but since the rate of charging up is probably proportional to the collecting area and inversely proportional to the electrical capacity, which is proportional to the radius of the balloon, the rate of charging up would be directly proportional to the radius of the balloon, and our measurements therefore give a lower limit to the rate at which a large balloon would acquire the potential of the air under similar circumstances. Two typical curves are shown

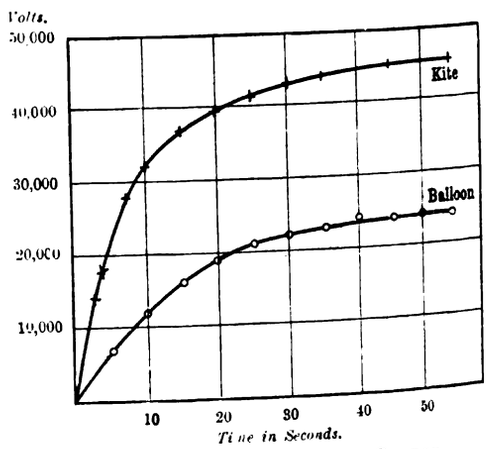

FIG. 2.—RATE OF ATTAINING CHARGE.

in Fig. 2. It may be assumed that the rate of charging up of the balloon at any instant is proportional to the difference of its potential from that of the surrounding air. On this assumption the potential of the balloon at any moment will be given by the equation $V = V_0(1 - e^{-\lambda t})$, where V is the potential of the balloon at any moment, V_0 the potential of the surrounding air, t the time in seconds reckoned from the beginning of the charging, and λ a constant. Investigation showed that the charge acquired was an exponential function of the time in agreement with the above assumption. The value of λ ranged from 0·06 to 0·25.

As a rule a kite acquired its charge considerably more rapidly than a balloon. This fact suggested that the rate of charging depended on the strength of the wind, for it was only in very calm weather that balloon ascents could be made.

* Abstract of a Paper read before the Royal Meteorological Society.

Experiments on the electrical state of the upper atmosphere have now been carried out by us during three consecutive summers, and it appears that results of considerable interest are obtainable by the methods employed. The problems of atmospheric electricity are, however, so complicated and seem to depend on so many conditions, that there is little hope of arriving at an understanding of the different influences at work by intermittent experiments. Recording instruments were attached to each kite or balloon to register the barometric pressure, the temperature, the humidity, and the wind velocity; but we have not considered it to be useful to publish these records, as we have been unable to establish any connection between these factors and the electrical conditions of the atmosphere. No doubt continuous observations similar to these described above conducted over prolonged periods would reveal the causes producing the large variations occurring in the electrical state of the atmosphere, and it is to be hoped that experimenters will be forthcoming who will be able to devote the necessary time to bringing such an investigation to a successful issue.

OPERATION OF TRANSMISSION SYSTEMS.

At the recent meeting in New York of the National Electric Light Association an interesting informal discussion took place on this subject. The following abstract is based on the account of the meeting given by the "Electrical World":—

Mr. MAX HEBGEN said that the most important factors in securing uninterrupted service on transmission systems were stated to be insulation, mechanical strength, general design of system and operation. He claimed that the factor of safety in the insulation of transmission systems as now employed was too low. For a 100,000-volt system the safety factor should not be less than three, for 50,000 volts it should be four, and for 20,000 volts it should be five. He considered that for all electromotive forces above 20,000 volts the suspension type of insulator was far preferable to the pin type. When the suspension type was employed no difficulty was encountered in obtaining the factors of safety mentioned above. He thought too much attention could not be paid to the mechanical strength of a transmission line where continuity of service was essential. Any wire larger than No. 6 gauge should be stranded; the wire stranded conductor with a hemp centre exposed more surface to wind and ice than did a 7-strand conductor of equal conductivity, so that the advantage of having all the wires subjected to the same stress was more than counterbalanced, and the 7-wire strand was altogether preferable. He said that the clamps for suspension insulators should be connected to the insulator by a hinge joint so that there would be little tendency to bend the wire when the insulator pulled in a direction other than perpendicular to the wire. Transmission lines feeding energy to an important load centre should be in duplicate or triplicate. They should preferably follow different routes, but where this was impracticable the different lines should at least be mounted on separate poles spaced far enough apart to prevent the possibility of one line interfering with another. The lines should be sectionalised by means of outdoor air-break switches, with a cross-over switching station at the middle of the line equipped with switches so arranged that one-half of either line might be cut out and the remaining section continue in operation. In any case where two or more lines supplied energy to the same point, the incoming lines should be controlled by reverse-power relays. Troubles from lightning could be guarded against by high insulation, the installation of one or more overhead earthed wires and the use of electrolytic arresters. Continuity of service depended equally as much on good operators as on good apparatus. In large systems all operations should be controlled by one man who had the position of load dispatcher. The importance of systematic patrolling of the line should not be overlooked.

Mr. J. P. JOLLYMAN (Western Power Co., San Francisco) in a written communication claimed that in order to eliminate interruptions to service power houses should be built on the unit system, only such cross-connections being used as were absolutely necessary for proper flexibility. It was especially essential that all apparatus which might need immediate attention in the event of trouble should be within the reach of every one. Relays should be used sparingly, if at all, because the power-house circuits must not be disarranged by any ordinary disturbances which might come in from the transmission system. The transmission line should preferably be constructed in duplicate on separate poles. In case only one pole line could be erected the arrangements should be such that one circuit might be kept in operation while the other was undergoing repairs. In order that trouble originating on one distributing line might not interfere with other feeders, fuses or relays were necessary on the distribution circuits radiating from sub-stations..

Mr. R. S. KELSCH in a written communication claimed that the most successful method of obtaining continuity of service from the high-voltage transmission line was to use the same factor of safety on the line as was employed in the power house with its reserve generators, duplicate bars, extra exciters, spare transformers, &c. A high factor of safety in insulation was of the greatest importance. Too much economy had been practised in the purchasing of insulators in the past; there were numerous transmission lines in operation to-day that should have a factor of safety in the insulators three times as great as at present.

Mr. W. N. RYERSON (Great Northern Power Co.) expressed the opinion that too much insulation might prove disadvantageous in low-voltage work.

Mr. F. B. H. PAINE (Niagara, Lockport and Ontario Power Co.) remarked that troubles on transmission lines were frequently hard to locate although easy to correct after being discovered. He mentioned the fact that certain line patrolmen now made use of automobile or bicycle head lamps in patrolling the line at night.

Mr. B. F. PEARSON (Southern California Edison Co.) stated that it had been found necessary to subdivide the 118-mile 75,000-volt transmission line in order to continue operation in case of failure to any one part of a circuit. He called attention to a peculiar fault of pin-type insulators upon which cracks developed on the interior petticoat, attributable probably to excessive temperature. Difficulty had been encountered with the pin type of insulator construction on account of birds standing on the steel cross-arms and stretching their wings to reach the live circuit above. This trouble could be overcome by the use of the suspension type of insulators. The interruptions to the Kern River transmission line totalled 160 in a year, most of which occurred during the spring season when the birds were more inclined to stand upon the transmission lines.

Mr. J. R. MCKEE called attention to the fact that the limit of increase in voltage to a transmission system was set by the corona loss rather than by the amount of insulation employed. Experience would seem to indicate that at the high altitudes in Colorado, 100,000 volts was about the limit; in Michigan, where a 110,000-volt system was operating without lightning arresters or overhead earth wires, no trouble was experienced from interruptions, probably on account of the excess of corona loss accompanying any abnormal increase in the voltage.

Mr. G. H. WALBRIDGE said that most of the troubles encountered on the system of the Central Colorado Power Co. had proved to be mechanical rather than electrical. Considerable trouble had been caused by the excessive wind velocities at the high altitude of 13,500 ft., at which a certain part of the transmission line was erected.

Mr. E. L. WEST (Central Colorado Power Co.) remarked that, on account of the condenser effect, when an electromotive force of 100,000 volts was applied on the 190-mile transmission system, an electromotive force of 150,000 volts was obtained at the far end. The clearance between wires had proved to be too small for the high altitudes encountered. By actual measurements made by Government officials, the wind velocity had been found to reach 165 miles per hour at the highest point of the transmission line. In order to prevent breakage of the transmission line, due to kinking, use was now being made of a flexible saddle for connecting the insulator to the line. The hemp-core, six-wire cable had proved satisfactory during the three years it had been in operation.

Mr. RYERSON remarked that the hemp-centre cable used by the Great Northern Power Co. had been found in good condition after five years of service.

Mr. R. G. BLACK (Toronto Electric Light Co.) stated that the six-wire hemp-core cable employed between Niagara and Toronto had given no trouble during the five years of service; the only interruptions to the 90-mile 60,000-volt transmission system had been those attributable to lightning. In May there were three interruptions, but in the previous nine months there was none.

Mr. P. H. THOMAS stated that the enormous currents produced on short circuit could be minimised by the use of series impedance combined with some automatic means of sectionalising the system.

Mr. PEARSON remarked that such a scheme was used in Southern California. It had been found that the synchronous apparatus was not thrown out of step during short-circuits.

PREVIOUS MAGNETIC HISTORY AS AFFECTED BY TEMPERATURE.*

BY PROF. E. WILSON AND L. C. BUDD.

It is well known that if a piece of iron be subjected to a considerable magnetising (previous history) force, and then be tested for permeability corresponding to a lower force, the permeability so obtained may differ widely from the permeability which would have been obtained had the material been previously demagnetised. The effects of previous magnetic history upon permeability and the dissipation of energy by hysteresis have already been studied† at ordinary atmospheric temperature. The object of the present Paper is to examine the effect of variation of temperature upon the influence of wide previous history. The material used has been in the form of rings built up from stampings of stalloy, which is an alloy of iron containing about 3 per cent. of silicon. The stampings are about 0·42 mm. thick, and have internal and external diameters of 32 mm. and 45 mm. Ring 1 was used for high temperatures, and had its windings insulated by hand with sheet asbestos. Ring 2 was used for low temperature, and had its windings insulated with silk. Particulars of the rings are given in the following Table:—

The method of test employs a ballistic galvanometer, and the temperatures are based upon a measurement of resistance of the second-

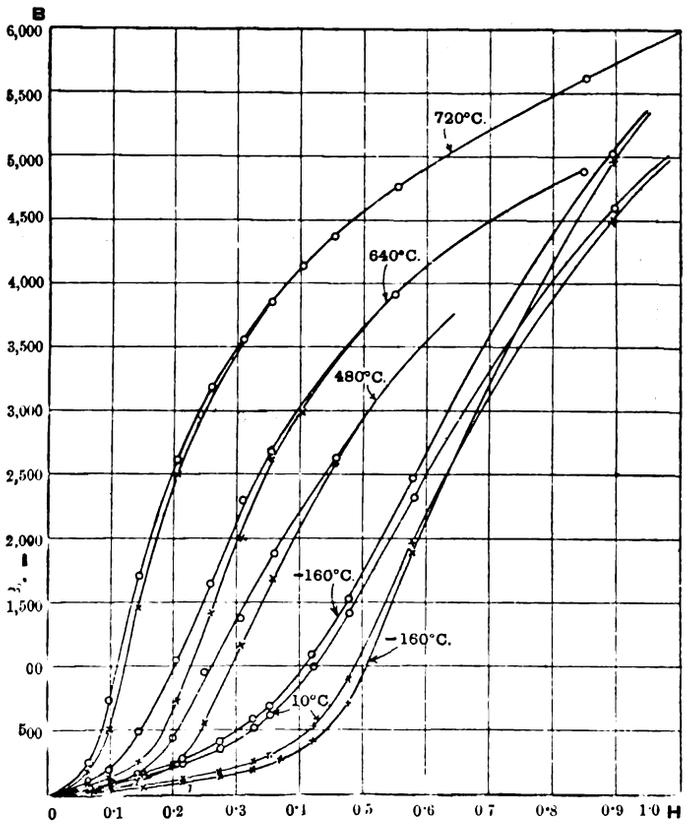

FIG. 1.

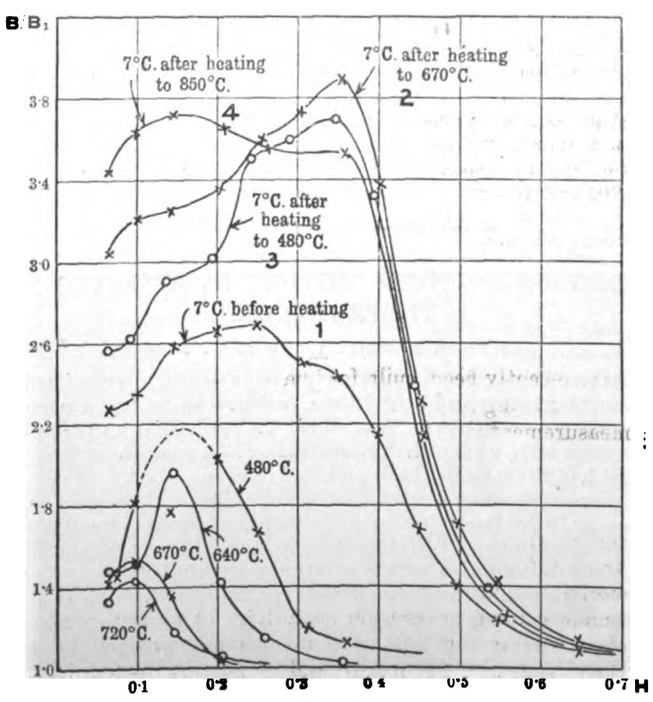

FIG. 2.

ary windings, care being taken that the magnetising force thus employed does not exceed the smallest reversal force used in the experiment. At atmospheric temperature and the temperature of liquid air the procedure was to determine the ordinary B—H curve after the material had been carefully demagnetised. This was done by gradually reducing the primary current given by an alternator at a frequency of 50. When dealing with high temperatures the ring was placed in a furnace heated by gas, and as the temperature was not absolutely steady in any one experiment, it was necessary to apply the previous history force immediately after taking the observation on the demagnetised ring, and then to demagnetise again for the next point, and so on. In all the experiments a previous history force of about 20 C.G.S. units was employed.

Fig. 1 gives a set of curves taken at various temperatures with and without previous history. In every case the upper curve was given by the demagnetised material, and the difference between it and the lower one is due to previous history. It will be seen that in liquid air the effect is most marked, and that it becomes smaller as the temperature increases. The material becomes non-magnetic at about 850°C., and regains its magnetic quality on cooling at 830°C. It seems safe to conclude that just before the temperature at which it becomes non-magnetic is reached the previous history effect has either vanished or become very small indeed.

In Fig. 2 the ratio of the magnetic inductions $B : B_1$ for a given value of the reversal force H, with and without previous history, is given. As received from the makers the material of ring 1 gives, at atmospheric temperature, curve 1. Atmospheric temperature curve 2 was obtained after heating to 670°C. and allowing the material gradually to cool. It will be seen that previous history effect is considerably greater after the specimen has been heated, and the other curves also confirm this, the increase being due primarily to a diminution of the permeability after application of previous history. With regard to the cooling experiment and ring 2, the curves in Fig. 3

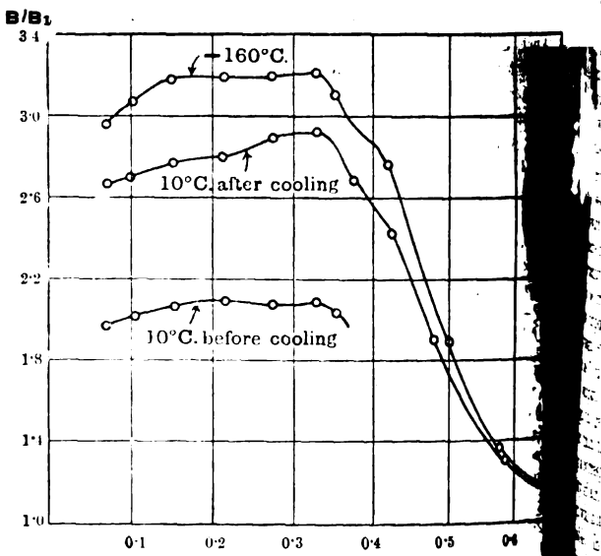

FIG. 3.

show that after the material has been cooled in liquid air, [illegible] vious history effect at atmospheric temperature is greater [illegible] first received, the increase being due to increased permeab[illegible] in the demagnetised condition. In spite of this, the effect o[illegible] history is greater at the temperature of liquid air than at at[illegible] temperature and it is less at high temperatures.

The conclusion is that the influence of large previous history in a 3 per cent. silicon alloy of iron is seriously a[illegible] variation of temperature, being largest at the low te[illegible] and ultimately becoming very small, if not vanishing, [illegible] near which the material becomes non-magnetic. In addi[illegible] heating and cooling have permanent effects upon the quality of this alloy. Previous heat treatment has also considered.

VENTILATION OF TURBO-GENERATORS.*

BY R. B. WILLIAMSON.

It is now universal practice to make turbo-generators [illegible] enclosed and to obtain the cooling by forced air circulation. [illegible] enclosing the generator the air currents can be more effectively directed to reach the parts where heat is generated and at the [illegible] time the noise is greatly reduced. The enclosed machine also [illegible] the advantage that air can be piped to it from outside or from [illegible] sources and discharged into the station, basement or outdoors, as [illegible] be required. The heat units in the discharged air represent [illegible]

* Abstract, based on accounts in the "Electrical World" and "Electric Railway Journal," of a Paper read before the National Electric Light Association.

per cent. to 6 per cent. of the total station output, and economy would dictate utilising these units for some useful purpose, such as pre-heating the air supplied to the boilers or maintaining a comfortable temperature in a factory. Arrangements are being made to accomplish the latter purpose in a large glass factory now being erected. The generating station is located alongside of the factory and the generators are arranged so that the air can be discharged either upward or downward. In summer the air can be discharged upward by removing a cover plate on top of the generator. In winter the outlet at the top of the generator can be closed and the air discharged downward into a large duct from which it can flow into the factory. The plant will ultimately have four 2,500 k.v.a. units, so that between 400 kw. and 500 kw. stored in the air will be available for heating. This plant will run continuously at full load, so that a steady supply of warm air will be available.

From considerations of the specific heat and weight of air and permissible temperature rise, the author shows that the quantity of air to be supplied should be from 100 cubic ft. to 150 cubic ft. for each kilowatt of internal loss in the generator; 125 cubic ft. is a fair value and will give good results if the circulation in the generator is such that the air can get at all parts where heat is generated.

In estimating the internal loss to be carried off by the air, the windage loss must be included, as this is one of the largest losses in a turbo-generator and contributes to the heating just as much as the core loss or copper loss. A turbo-generator run on open circuit with no excitation and no loss in it other than the windage will show quite an appreciable rise in temperature, in extreme cases as much as 12°C. to 15°C. A great deal of windage loss is due to the skin friction of the rotor, and is independent of the fans. The passage must be arranged so that the air will be guided through the generator with as small an amount of friction as possible.

In a 60-cycle generator of 5,000 k.v.a. (normal) output, running at 1,800 revs. per min. and operating at unity power factor, the internal losses might be as much as 220 kw. Allowing 125 cubic ft. per kilowatt loss, this generator should have about 28,000 cubic ft. per minute for satisfactory cooling. This amounts to 2,270 lb. of air per minute, or over 60 tons per hour. The total internal loss will usually be from 4 per cent. to 6 per cent. of the rated kilovolt-ampere output, being a larger percentage for the smaller machines. As a rough estimate, therefore, the allowance of cooling air may be taken as 5 cubic ft. to 7½ cubic ft. per minute per kilovoltampere rated output. On the above basis the weight of air to be passed through the generator end of a steam turbine unit is in many cases greater than the weight of steam passed through the steam end during a corresponding period of time. In order to handle this large quantity of air, careful attention must be paid to the ducts or pipes through which it is supplied, and the air should be as clean and cool as practicable. In some cases it may be drawn directly from the basement, but this should not be done if the space below the generator is occupied by auxiliaries which heat the air.

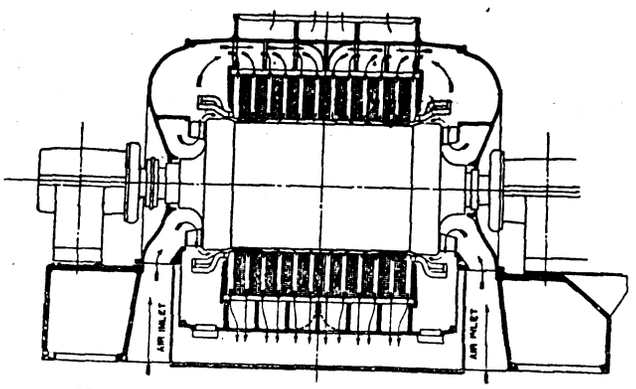
In case cool air cannot be obtained from the basement a pipe or duct should be run outdoors and the opening protected so that rain or dirt cannot be drawn in. Ducts should be as straight as possible and of such cross-section that the air velocity will not exceed 1,000 ft. to 1,200 ft. per minute. When air is drawn from outdoors it is advisable to have dampers arranged so that it can, if necessary, be taken from the basement in cold winter weather.

The air also should be clean. The quantity of air passed through a generator is so large that even a small percentage of dust soon results in a large amount of dirt within the machine. In Europe a great deal of attention has been paid to the cleaning of the air, and numerous forms of air filter have been devised. A filter can be easily made by stretching cheese cloth, cotton or thin flannel between two frames. The cloth is passed around flat strips of galvanised iron and is pulled taut by nuts on threaded studs at each corner. The cloth is threaded back and forth so that the entering air has a large surface of cloth to pass through. The velocity of the air through the cloth is, therefore, very low and a filter unit approximately 3 ft. wide, 3 ft. high and 2 ft. deep can pass 2,000 cubic ft. of air per minute with an air velocity through the cloth not exceeding 10 ft. per minute. With this low velocity the filter does not throttle the flow of air to any great extent, and with the large area so obtained the cloth will not clog up rapidly. By constructing the filter in units as many units as may be required for a given machine can be set in a framework to form a wall through which the air must pass before reaching the generator.

Air filters should be mounted so that they can be easily taken out at intervals and cleaned. Unless they are cleaned from time to time they will become worse than useless by cutting off the air supply entirely. Even when they are provided, the interior of a turbo-generator should be cleaned periodically.

Many different plans have been used for passing the required amount of air through the limited passages within the machines, but the usual practice is to set up the air circulation by means of centrifugal fans at the ends of the rotating field structure. In some cases the air has been supplied by separate centrifugal blowers in the same manner that is customary for an air-blast transformer. This arrangement is advantageous in that the fan can be designed for the highest possible efficiency and the flow of air through the generator can be controlled at will, but is slightly disadvantageous in increasing the number of station auxiliaries.

The major portion of the heat to be dissipated is produced in or at the stationary armature core. According to a method of ventilation extensively used in both this country and Europe, air enters intakes in each of the end housings and after passing through the fans flows into a chamber at the bottom of the stator yoke, whence it is forced through the ducts in the stator core and out at the top. The air divides into two streams, one-half passing up through the core on each side of the machine. With a generator of large diameter the paths for the air become long and the temperature rise correspondingly high.



VENTILATING ARRANGEMENT OF TURBO-GENERATOR.

For large high-speed units a better method is the one illustrated herewith. Instead of passing all of the air up through the machine according to the two-path plan it is introduced behind the core through a number of inlets distributed around the whole periphery and after passing through the ducts is discharged into adjacent chambers. Several advantages are claimed for the multi-path method of ventilation for large machines. One-half of the outside circumference of the stator punchings is exposed directly to air from the fans and the stator is not dependent for its cooling on hot air that has already passed over the rotor before reaching it. The use of a number of short paths in parallel through the core greatly reduces the resistance offered to the flow of air, thus, for a given pressure, allowing a much larger quantity of air to be passed through the machine, or, on the other hand, allowing the use of lower pressure for a given flow.

Petrol-Electric Motor Cars—The "Electric Railway Journal" gives a description of a petrol-electric car, six of which have recently been built for the "'Frisco" lines. These cars are 70 ft. long and 10 ft. 5 in. wide overall. The width, inside measurement, is 9 ft. 6 in. The seats are nearly 4 ft. long, and, as they have no arms, three people can comfortably occupy one of them. The aisle is narrower than is customary on steam railway cars, but, nevertheless, is wider than on many electric cars. Apart from the passenger compartment, which seats 98 persons, the car has a 6 ft. baggage compartment. The petrol-electric equipment consists of an eight-cylinder petrol engine driving an electric generator. The motors are of the standard railway type, and the car is controlled by varying the voltage of the generator and connecting the motors in series or parallel as required. The engine control consists of a combination air valve and gas throttle, by which the engine is started on compressed air, but as soon as it begins running on petrol the air is shut off. With this arrangement the engine need be run only when the car is working. The auxiliary equipment includes a petrol-electric set for lighting and means for securing compressed air. The car described has a maximum speed of about 50 miles per hour on level track, and a scheduled speed of 25 miles per hour with stops 2½ miles apart.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d.

LONDON COUNTY COUNCIL LOANS.

A short discussion at the meeting of the London County Council on the 1st inst. gave prominence to some questions of much interest to those concerned in the supply of electrical energy in London, either Metropolitan Borough Councils or Companies. The occasion was a report of the Finance Committee presented for confirmation by the Council, which recommended the sanction of a long list of applications for loans. These applications were from no fewer than 15 Metropolitan Borough Councils, and the amount sanctioned by the Finance Committee and submitted for confirmation by the County Council amounts in the aggregate to about £133,000, which sum must be increased to £148,700 by a loan of £15,700 sanctioned a week previously to Stepney Borough Council for electricity purposes. Of this total, £71,720, or thereabouts, was proposed to be borrowed by Borough Councils for their electricity undertakings, the remaining £77,000 for building town-halls and offices, for street improvements and other purposes.

Mr. HENRY L. CRIPPS, the recently elected alderman, stated that, although he would not then attempt to criticise the policy of the Finance Committee, he thought the general policy of these loans, especially under the altering conditions of the population and ratable value in London, demanded a complete reconsideration. He referred both to the general policy of these loans and to the policy in the case of municipal electricity undertakings;

Digitized by Google

it is with the latter, as being more closely interesting to our readers, that we propose to deal.

The expressions "borrowing" and "loans," to denote the operations in question, are wanting in exactness. We may explain this in more detail later, but for the present purpose it may be well to make clear that no money is, either borrowed or lent in the strict meaning of the words. Money standing to the credit or raised for the purpose of the County Consolidated Fund is advanced to the Borough Council, which in its turn shunts the liability for replacement on successive future generations of borough ratepayers, from whom must be levied, by way of a charge on their own revenue or the borough rate, annual sums payable to the County Fund sufficient to replace the advance in a given number of years.

The real transaction, therefore, is one to which the future county ratepayers and borough ratepayers are committed by the County Council and the Metropolitan Borough Councils respectively, the obligation of the borough ratepayers being to pay up the annual instalments to the County Fund, and the obligation of the county ratepayers being, in case of default by the Borough Council, to make up the deficiency themselves. The enterprise, to the financial consequences of which in the future both sets of ratepayers will find themselves committed, is one in whose inception, of course, they had no choice, and as to which, if it turn out ill, they can have no redress.

Alderman CRIPPS made an interesting point of the fact that this year the ratable value of London, for the first time since the introduction of the assessment system some centuries back, had failed to show the constant progressive increase which had been hitherto maintained; while the census showed that this year, for almost the first time since the Roman era, the population resident within the county boundary had ceased its normal rate of increase. It is obvious that if the aggregate ratable value of London diminishes, the rate in the £ required to produce a given sum must increase proportionately. The general annual expense of London's public requirements is not likely to diminish. Moreover, the charges we are now discussing, and the dates by which they must be met, are absolutely fixed in advance. It follows, therefore, that whatever amount in the £ may be the liability imposed on the ratepayers in respect of these loans, it must become proportionately increased automatically if the tendency of the ratable value to diminish now indicated continues.

Alderman CRIPPS expressed the opinion that events have proved that the investors in this country have "underestimated the risks of investment"; in other words, they have been generally satisfied with a rate of interest inadequate to secure them against loss on realisation of principal. He instanced the case of Consols, where the investor, having received interest on his investment for nine years at less than $2\frac{3}{4}$ per cent., now finds that he can only realise £78 for the £100 Consols which he perhaps bought in 1901—only 10 years back—at 98, and as lately as 1906 at 91. Is it prudent, in the face of this lesson, for the London County Council to force the county ratepayers of the future (*volentes nolentes*) into an investment for a fixed period at $3\frac{3}{4}$ per cent. per annum on which (if it be as free from risk as the "premier" security seemed in 1906) they may in five years' time have lost 13 per cent. of the principal? Of course we are aware that the two cases are not exactly analogous; but similar lessons may be learnt from the depreciation in market value of London County stock during the same period.

For an exact forecast of the possible consequences of these loans we must take account of the operation of the sinking fund and the ratepayers' liability with respect to it, and we should also require an estimate of the amount to be yielded in future years by the levy of a rate of a certain amount (say one penny) in the £ on the then ratable value of the county.

Apart from these general considerations, which cover all advances for whatever purpose by the London County Council to Metropolitan Borough Councils, including electricity works, the present condition of the London electric supply question was referred to by Mr. CRIPPS as largely affecting the policy of loans for electricity purposes, especially for new machinery and patchwork purposes at existing stations.

It has been generally admitted among those who have considered the subject in the light of practical experience that combination or consolidation in some form of the electrical undertakings of London is desirable in the public interest. During the last few years Parliament has considered two large schemes for attaining this object. Each in turn failed to command approval. Neither had been sufficiently worked out so as to avoid objections. In the first, it was sought to incorporate a new company which would generate electrical energy in large quantities at stations suitably located, and supply it in bulk to the municipal and commercial undertakers, who in their turn would supply direct to those wanting power. The second scheme proposed the setting-up of the London County Council as the body to generate and supply in bulk to the municipal and commercial undertakers. It is not necessary to repeat the objections which were deservedly fatal to both these schemes at the time.

An alternative proposition which was brought forward in 1908 by the electric supply companies, obtained general assent, and the London Electric Supply Act of 1908 was passed, which provides for combination by agreement among the municipal and commercial undertakers, so that the separate stations and works of all may be made more readily available for the supply within the whole area with greater efficiency and economy. Mr. GORDON, the member for Whitechapel, who has devoted much thought to the subject in Poplar and Stepney, made a strong point of this in the recent discussion. If there is to be any combination of this character, it follows that the entire system now prevailing must undergo radical alteration. Instead of some 14 Metropolitan Boroughs and 13 or 14 companies, each with independent stations and systems designed to meet the requirements of their particular district only, there would be one body, working one comprehensive system designed to meet the requirements of the whole. A great saving of expenditure would be the result. Suppose it

Digitized by Google

came to pass that the London County Council should exercise its statutory powers of purchasing the undertakings of the companies, it seems clear that the municipal undertakings must be taken over at the same time, and every piece of patchwork made by the Borough Councils by means of money "borrowed" from the County Council must either be purchased or made the subject of compensation, or be thrown upon the "scrap heap" as waste material. The ratepayers of the future must continue to discharge their obligations to provide the instalments necessary for the extinction of the "loan," although the machinery purchased and installed by the money borrowed had ceased to be productive or to have any value.

The electrical companies of London have had a great opportunity of acting under the legislation of 1908 and formulating a scheme to solve the great problem of the supply of London. So far they seem to have failed. We recognise the difficulty of amalgamation. Each board of directors has its own shareholders' interests as its primary motive, and any reductions in the number of chairmen, directors, engineers, managers, secretaries and their salaries all present considerable difficulties. The only possible method of settling these difficulties seems to be arbitration, to which it is understood some at least of those concerned decline to commit themselves. On the occasion of the discussion by the London County Council to which we have referred there seemed to be a concensus of opinion that if the Companies and Borough Councils maintained longer their policy of inaction Parliament must be asked to provide some means of making the Act of 1908 effective. It is to be hoped that compulsion of this kind will not be necessary, and that the initiative will be taken by those most immediately concerned.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. And 10 per cent. for abroad or for foreign books.)

Lignes Électriques. Part I., "Aériennes," by PH. GIRARDET. pp. 181, 5fr. Part II., "Souterraines," by PH. GIRARDET and W. DUBI, pp. 207, 5fr. (Grenoble, 1910: Jules Rey.)

These two books, written primarily for engineering students, have a lucidity and conciseness, typically French, and M. Girardet's work would seem to deserve the praise given to it in the preface by his former teacher, Prof. Pionchon, of Dijon.

The treatment of both systems of electrical distribution is limited to that of actual construction, the reader being assumed to have studied elsewhere the theory of the stresses in lines and supports, and the methods of calculating feeders and networks. The practical and economic features touched upon are of considerable interest, although English and French practice differ materially in both overhead and underground installations.

In Part I. supports for aerial lines are discussed very fully, and the author unhesitatingly proclaims the superiority of reinforced concrete, on account of its advantages in strength, absence of maintenance charges, possibility of long spans, and a lower cost than that of lattice poles.

The question of relative maintenance can be appreciated when, as the author shows, with the lattice type the cost of painting the 1,700 towers required along a line 70 miles long is over £1,000. The weight of reinforced concrete in transport is its chief drawback, and this can only be overcome on long lines by manufacturing the poles on site. The author is so convinced of the value of reinforced concrete that he devotes 12 pages to specifying closely the selection of the materials, the construction of the steel skeletons, the process of moulding the poles, and the general organisation of the operations. So complete and clear is this portion of the book that a good line foreman, without previous experience, but armed with this description, could undertake the construction of a run of ferro-concrete poles with every chance of success.

The surveying of the line, settlement of way-leaves, and the removal of obstructions are dealt with in a very practical way. The actual work of pole planting, erection of towers, fixing the wires, and the efficient management of labour and stores are fully described and partially illustrated.

The design of insulators is not considered theoretically, but some excellent hints are given on the choice of those actually to be used, and the tests they ought to satisfy. The engineer is warned of the folly of attempting to save a few pence per insulator if it entails any risk of breakdown. Copper is assumed as the material for the overhead line in detailing the various operations, but in an appendix a useful summary is given of the properties of aluminium, its handling in line construction, and the conditions of economy which justify its use.

The remainder of the volume is taken up with the legal precautions to be adopted in documents relating to concessions, way-leaves, and the various Government regulations affecting the establishment of lines on public roads, or on private property.

Part II. treats of underground mains, and although it is well arranged and printed, it suffers, like Part I., from a scantiness of illustrations. The authors waste no words in preamble, but proceed at once to describe in detail those practical points with which the technical student must become acquainted, after he has devoted some time to the theory of insulated conductors and networks, if he wishes to qualify as a mains engineer.

The design of a network is only commented upon in order to emphasise its difficulties, and the reader is recommended to accept the results of experience as at least equal in value to those obtained from theory—in many cases not an unwise counsel.

The relative merits of the various classes of underground mains are summed up in the authors' opinion that there is nothing better than armoured, lead-covered, paper-insulated cables, laid direct. Lead-covered rubber mains are dismissed in a single page, as only of historic interest. Descriptions of joint boxes and other cable accessories are simplified by being confined to those for armoured cables only, with the further restriction that any modern supply would be three phase with three-core mains for high tension and four-core for low tension. The popularity of armoured cables in Continental practice is probably due to the great care taken in the actual laying, the provision of a bed of sand in the trench, always being deemed indispensable.

The authors very properly attach great importance to the influence of cost of copper in mains work, and in the second chapter the youthful practitioner is initiated into the mysteries of the latest making-up prices as given in the "Mining Journal." The book abounds in useful hints of this kind. In the twenty odd pages devoted to joint and disconnecting boxes, only one illustration is given, but in spite of this the authors contrive to convey a great deal of useful information as to the general principles of the construction and use of these accessories. The tests of conductivity, insulation and capacity, which must be carried out before cables are accepted from the makers, are concisely stated.

The best section of the book deals with a topic which is rarely considered worthy of a detailed description, but which has a marked effect on the life and service of the cable, *i.e.*, the conditions attending the preparation of the trench, and the drawing-in of the cable.

The authors are fully alive to the importance of the work done by the humble navvy, and dwell with minute care on every step in the sequence of mains laying, from the

Digitized by Google

out of trial holes to the final reinstatement of the road surface. While giving valuable technical precautions for the avoidance of damage due to sharp bends in the cable, and laying during cold weather, they do not lose sight of the economies to be effected by careful methods of store-keeping, keeping of accounts, and good management of labour. An excellent condensed account is given at the end of the book, of methods of fault location, with several examples taken from notes of the more troublesome faults actually met with in the authors' practice. This part of the book is in less prominent type, conveying the suggestion that the section will be rarely referred to if the authors' precepts for mains laying are carefully followed!

On the whole this is a useful and illuminating little treatise on the everyday side of mains work, which academic tuition from lack of knowledge or of interest is inclined to ignore.

J. R. DICK.

Automatische Fernsprechsysteme. By A. B. SMITH & F. ALDENDORFF. Parts I. and II. (Berlin: S. Heimann & Sohn.) Part I., pp. 160, M. 3. Part II., pp. 161–327, M. 5.

This book is based on A. B. Smith's "History of the Automatic Telephone," published in "Telephony" (Chicago), and deals in a very interesting manner with the development of automatic systems. The production is, however, largely of historical interest, as, unfortunately, the description (particularly of the Automatic Electric Co.'s system) closes without any lucid particulars of the two-wire system, now being introduced in San Francisco and Chicago, and looked on as the latest and standard practice, and, therefore, of the greatest interest to the engineer.

The first volume gives descriptions and diagrams of the early inventions in the automatic field; the work of the brothers Connolly, McTighe, Smith, &c. The early forms of the system of the brothers Strowger, the work of Lundquist and the brothers Erickson. The remainder of this volume deals with the improvements in and development of the Strowger system by Keith and others: the use of the connectors with contact banks and the associated circuits; party-line working; impulse senders on instruments; group selectors and a description of the early installations.

The first exchange in which the calls were registered was in Chicago, a meter being associated with the first selector, which only records when the necessary impulses are sent to a line that is disengaged but does not respond when the line is busy, and is then automatically returned to the former position when the receiver is replaced. The later practice, however, is to associate the meter with the line switch, and it only registers when the called subscriber answers, but this is not mentioned. This volume finishes with a few details of the construction of the Automatic Electric Co.'s relays and connectors.

Volume II. goes into further detail of later installations of the three-wire systems, that of Los Angeles being interesting, as it is the largest and one of the latest systems so wired. A section deals with the layout and wiring of the plant. Another with the Keith line or individual switch, the perspective views showing the two-wire switch, but the diagram the three-wire one. A page and a third are given to the economy and the suitability of this system to decentralisation. A later system of party-line working is described, and also other installations. The last chapter on the Automatic Electric Co.'s system describes inter-exchange working and the signal repeater which repeats the impulses sent from the sub-station, beyond the condensers in the circuit at the first exchange, to the apparatus at the second.

The Lorimer system is described in the following 63 pages. This is a power-driven system, certain parts of which are continuously revolving. The lines end in no individual electromagnetic devices, but in terminals which are wiped over by brushes so that both the calling and the called lines have to be selected. The system is most ingenious and interesting, but the circuits are very involved. These are, however, described in considerable detail. It is noticeable, however, that the illustration of the instrument impulse sender switch is not of the latest type.

A description of the Clement auto-manual system is given as typical of semi-automatic systems, in which the sub-station instruments are without impulse senders, the operator calling the required line.

The sections or chapters of the books are not numbered, and the division of the work into two volumes is in the middle of a chapter.

W. A.

ACCURACY OF THE BELLINI-TOSI WIRELESS "COMPASS" FOR NAVIGATIONAL PURPOSES.

BY L. H. WALTER, M.A.

Summary.—The author gives results of actual working of the Bellini-Tosi wireless compass.

While there is little doubt that some recent mishaps at sea have again drawn attention to the valuable service which can be rendered by wireless telegraphy, in facilitating rescues, they may also be considered to demonstrate that the ordinary wireless equipment is no actual safeguard against collision or stranding, &c., in time of fog—for wireless telegraphy apparatus was carried by the North German Lloyd liner "Prinzessin Irene," by the Ward Line steamer "Merida," and by H.M. Canadian cruiser "Niobe," to mention only three examples.

By the use of a directive system of wireless telegraphy it is known that the bearing of fixed or moving stations can be readily determined, but no results have hitherto been available. For this reason it appears desirable that some actual figures should be published in order to give an idea of the accuracy with which a ship can be navigated by means of the Bellini-Tosi wireless compass during fog or in thick weather.

The arrangement itself has already been referred to in THE ELECTRICIAN (Vol. LXV., p. 861, 1910), and consists, as is known, of a comparatively small size directive receiving set; the actual size only depending on the dimensions of the ship upon which it is fitted.

The provision of such a directive arrangement on board ship has several advantages, the most important being that the ship's navigating officers are able to make the observations themselves with any care they like. In other methods, such as informing a ship of its position by means of wireless telegraphy, it is necessary to have a directive arrangement at the shore station, and even in such a case the danger of collision between ship and ship is in no way lessened.

Experiments were carried out between the Dieppe station and the destroyer "Bombarde," of the French Navy, and also between the Boulogne-sur-Mer station and the armoured cruiser "Bouvines." The Dieppe station was provided with triangular directive aerials 50 metres in height; the wavelength used by the "Bombarde" was 300 metres. The following table shows the results, the fourth column giving the differences between the bearing as determined by the radiogoniometer and that as deduced from the vessel's course.

Table I.

Observation No.	Bearing from Radiogoniometer.	Bearing from ship's course.	Difference.
1	North 48° W.	North 43° W.	+5°
2	N. 39° W.	N. 36° W.	+3°
3	N. 33° W.	N. 27° W.	+6°

10	N. 46° W.	N. 42° W.	+4°
11	N. 60° W.	N. 59° W.	+1°

The errors shown in column 4 are all positive, the mean error being 5 deg. An examination of the radiogoniometer after the trials showed that this error was due to a faulty setting of the pointer, which was found to be clamped in a posi-

Digitized by Google

tion about 5 deg. displaced in the direction which gave rise to the positive error.

The Boulogne-sur-Mer station has already been described in THE ELECTRICIAN (Vol. LXIV., p. 421, 1909); the results obtained in the tests between this station and the "Bouvines," which used a 300-metre wave, and was cruising in sight of the English coast, are shown in Table II.

Table II.

Observation No.	Bearing from radiogoniometer.	Bearing from vessel's course.	Difference.
1	North 72° W.	North 74° W.	−2°

17	N. 21° W.	N. 19° 30′ W.	+1° 30′
18	N. 19° W.	N. 17° W.	+2°
19	N. 18° W.	N. 14° W.	+4°
20	N. 14° 30′ W.	N. 11° W.	+3° 30′
21	N. 6° W.	N. 5° W.	+1°
22	N. 8° W.	N. 7° 30′ W.	+0° 30′
23	N. 13° 30′ W.	N. 11° 30′ W.	+2°
24	N. 14° 30′ W.	N. 12° 30′ W.	+2°
25	N. 13° W.	N. 12° W.	+1°
26	N. 16° W.	N. 14° W.	+2°
27	N. 16° W.	N. 16° W.	0°
28	N. 19° 30′ W.	N. 17° 30′ W.	+2°
29	N. 21° 30′ W.	N. 18° 30′ W.	+3°
30	N. 21° W.	N. 21° W.	0°
31	N. 26° 30′ W.	N. 22° W.	+4° 30′
32	N. 28° W.	N. 23° 30′ W.	+4° 30′
33	N. 30° W.	N. 25° 30′ W.	+4° 30′
34	N. 32° W.	N. 28° W.	+4°
35	N. 33° W.	N. 31° 30′ W.	+1° 30′
36	N. 34° W.	N. 34° 30′ W.	−0° 30′

In this case there are two distinct groups of errors, positive and negative, and it is considered by Bellini and Tosi that these are probably due to the deviations of the magnetic compass on board, caused by the ship's sides, according to the different routes followed. The mean of the errors, taking their sign into consideration comes out at 0° 20′ only, while that of their absolute values amounts to 2°. The accuracy of the observations may thus be considered quite satisfactory.

The arrangement of a directive aerial for navigational purposes on board ship has been called a "wireless azimuthal compass," owing to the fact that like its optical equivalent the goniometer or taximeter it enables us to measure the angle which a direction makes with the axial centre line of the ship. The wireless compass has, however, a range which is generally greater than that of the taximeter; on the other hand, while the taximeter gives both direction and sense of the observed point, the wireless compass gives only the direction: the sense has to be obtained by two simultaneous or successive observations.

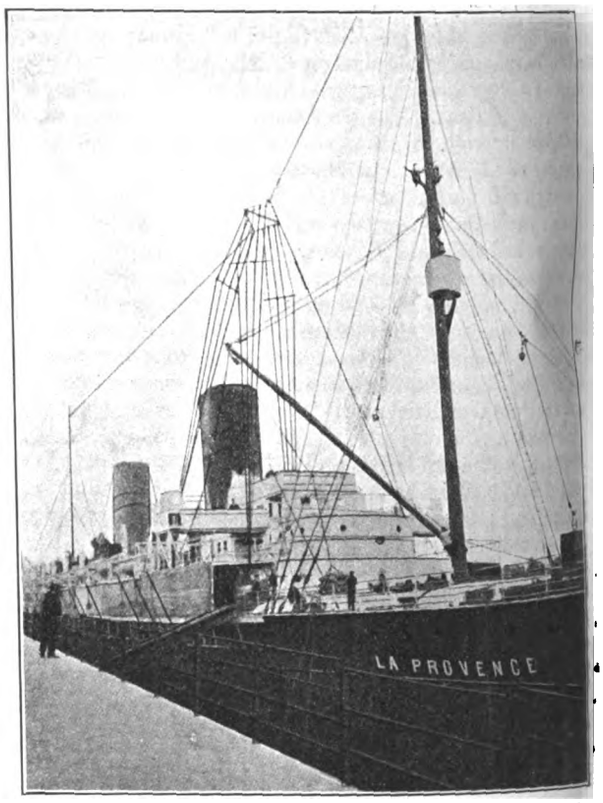
The general arrangement of the "compass" aerial on board a passenger liner is well shown in the accompanying photograph of the "Provence," of the Compagnie Générale Transatlantique. This vessel is fitted with the Marconi system for ordinary wireless communication, but carries in addition, for safety in navigation, the submarine bell signalling apparatus and the Bellini-Tosi wireless compass.

As an instance of the information which the wireless compass affords the navigating officer, the following short log of a trip of the "Espagne" (a sister ship of the "Provence") from Havre to Saint-Nazaire is of interest.

The departure from Havre took place at 1 p.m. At 4:30 the "Espagne," being in sight of the lighthouse at Barfleur, the direction of the Niton station was determined. The bearing, as found by the wireless compass, was 75° on the starboard bow, which was found to agree with that deduced from a knowledge of the ship's position. The distance between the ship and the Niton station was 60 miles, and the signals received were so strong that they could have been made out at a much greater distance. The wave-length of the Niton station was 300 metres.

From 5 o'clock to 5:15 the direction and movements of several vessels were determined, some going north, the others south; the direction of all of these lay between 5° on the port bow and 17° on the starboard bow. At 1:15 a.m. a station was heard at 50° on the starboard bow. At 8:55 a.m. a station was located in the direction of the vessel's axis. At 9:45 a.m. a station at 35° on the starboard bow.

From 9:55 onward a large number of signals were received, of different wave-lengths, all lying between 0° and 20° on the starboard bow. Eventually a French squadron cruising off Lorient was perceived. The signals just referred to were those from the ships of this squadron, so that at the time the signals



VIEW OF S.S. "LA PROVENCE" SHOWING ARRANGEMENT OF THE "COMPASS" AERIAL.

were received the ships were all within the angular zone determined by aid of the wireless compass.

In the same way as with the fixed directive stations the accuracy with which the bearing can be determined by means of the wireless compass was investigated in the course of a lengthy series of trials. For this purpose the French cruiser "Carnot" was equipped with a compass attachment, and carried out the tests at Brest, with the cruiser "Bouvet" and the Brest–Kerlaer station as transmitting stations; the former having a 600-metre wave and the latter one of 300 metres.

The results are shown in Table III., which is typical of many series of observations; the trials in this case having been made with the Brest–Kerlaer station as transmitter. This station was working with reduced energy and a small spark, and yet the signals were well received on the short "compass" aerials at 12 miles, while the signals from the "Bouvet" were very strongly received at 19 miles, so that a greater range could easily have been obtained. The range is nevertheless considerably greater than that at which optical measurements are generally taken.

14	54° „	57° „	−3°
15	60° „	61° „	−0° 30′

A very important fact has also been established as a result of the numerous tests, and that is that the radiogoniometer gives the same accuracy on board as on land, the masses of metal on the ship exerting no noticeable influence on the indications of the apparatus. In view of these positive results the French Minister of Public Works has decided to equip three "radiophares," or lighthouses with short-wave wireless apparatus, as an aid to navigation and for the benefit of ships fitted with the Bellini-Tosi wireless compass. One installation is to be placed on the lightship "Le Havre," about 7 miles from Cap de la Hève, near Havre, while the other two, to facilitate entry to the port of Brest, are to be located in the lighthouses on the Ile de Sein and at Creach d'Ouessant respectively. The signals to be emitted in time of fog have been fixed as follows: Havre, the letter H (spark note 522 per second); l'Ile de Sein, the letter S (spark note 783 per second); Creach d'Ouessant, the letter O (spark note 522 per second). The signals are to be emitted every 30 seconds and to be repeated *slowly* for at least ten seconds. The wave-length chosen is 80 metres.

CORRESPONDENCE.

UNITS OF RESISTIVITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: While heartily agreeing with Mr. Dellinger's conclusions as to the advantages in certain cases of using the mass resistivity, I most strongly protest against the unscientific names which he uses for the units. He is quite correct in thinking that the introduction of the unit cube into the definition of resistivity has been the cause of much confusion of thought, which, in my opinion, is not confined to students, but extends in many cases to their teachers, text-book writers and even examiners. The slip-shod use of "ohms per cubic centimetre" has been largely responsible for this, but "ohms per grammemetre" is every bit as bad. The best definitions are: "Resistivity is that property of the material in virtue of which it converts energy into heat when an electric current flows through it, and it is measured by the *resistance per unit length of a rod* (or wire) *having a unit cross-section*." "The mass resistivity is measured by the resistance per unit length of a rod (or wire) having unit mass per unit length." The units of length and mass belonging to the system which includes the joule, watt, ohm, &c., are the metre and kilogramme, but a unit of resistivity may be obtained by using any units that may be convenient for the purpose on hand. The microhm-millimetre and microhm-inch are of convenient magnitude, but of course it is not necessary to measure the length in the same unit as that involved in the unit of cross-section. Mr. Dellinger's "ohms per centimetre cube" ought to be "ohm-cms.," his "ohms per metre-millimetre" ought to be "ohms-mms.^{2} per metre," his "ohms per mil-foot" should read "ohms-mils^2 per foot," and his "ohms per metre-gramme" is "ohm-grammes per metre^2."

It is generally agreed that if a and b be any units, a per b means a divided by b, and a-b denotes a multiplied by b. Familiar examples are "miles per hour," "lbs. per cubic foot," "foot-pounds," "foot-pounds per minute," and so on. Unfortunately a few exceptions to these rules have come into common use among "practical" men, partly because of inaccurate conceptions of the relations between the quantities, but chiefly because of that human weakness which makes us all prefer to call a thing by some other than its correct name, especially when the substitute is the shorter of the two. The number of such is at present small, but some have already got such a good foothold and are so convenient to use, that it will be very difficult to dislodge them from a position they ought never to have occupied. Such are, for instance, "candle-foot," "megohms per mile," "ohms per centimetre cube," and "ohms per metre-gramme."

Of course, all of us who are in the habit of using such expressions know exactly what is meant by them, and so many will say that it is pedantic to quibble at them. How many of those people, I wonder, who condone, and even encourage, this production of new exceptions to our rules, are also advocates of the removal of some of the disadvantages under which we labour owing to the ignorance of our ancestors by the heroic means of changing all our weights, measures and coins. If such a gigantic task is too much for us to do for posterity, we can at least see that we do not add any more which will have to be reformed later. For ourselves, it is easier to continue in the way to which we have been accustomed, but each new exception to our general rules for forming and naming units has to be separately learnt and retained in the memory by each succeeding generation; and it thus constitutes an additional burden on all those who come after us, and another encumbrance to them in their pursuit of new knowledge.

Compare, for instance, "Board of Trade unit" with "kilowatt-hour," or "henry" with "secohm" (now, alas! almost forgotten). Both names of each pair stand for the same thing, but the first one is a special convention and has to be remembered as such, whereas the second tells us on the face of it what it is in terms of more familiar units.

If we don't wish our units to resemble the spelling of our language—each word a law unto itself—we must keep the number of special names down to the lowest possible limit, restricting them entirely to quantities whose use is so frequent that the names soon become quite familiar. It is only in such cases that the advantage of a short special name outweighs the disadvantage of having something additional to memorise. Above all, we must not permit exceptions and direct contradictions to our regular rules on the subject.—I am, &c.,

Merchant Venturers' Technical College, DAVID ROBERTSON.
Bristol, August 12.

New Technical Museum at Vienna.—In commemoration of the 60th anniversary of the Emperor Francis Joseph's reign, Austrian manufacturers, with the assistance of the State and the City of Vienna, have initiated this new museum. The foundation stone was laid on June 20, 1909, and the building, which covers an area of about 20,000 sq. yds., is now nearing completion, and will be a lasting monument of the long and memorable reign of the present monarch.

The technical museum has been established to demonstrate the development of industries and crafts in historical succession, also to do justice to the technical achievements of the present day and to promote industrial progress by periodical exhibitions. It is to be a public educational centre spreading the knowledge of the scientific foundations and technical pursuits of the empire. A considerable stock of objects has been secured, as several large and valuable State collections, till now dispersed, are shortly to be brought together. Many links in the chain of technical development are still missing, and therefore technical scientists, manufacturers and craftsmen of all countries are invited to co-operate in the great task and to assist the museum in procuring and selecting suitable objects. Everything appertaining to technical labour is acceptable, and especially tools, machines, apparatus, models, materials, methods of working, finished articles, as well as plans, designs, books, illustrations and manuscripts. The Austrian Government has placed at the disposal of the museum the spacious halls of the Rotunde for storing and selecting donations. The names of donors will be perpetuated by inscription on the gifts and in a memorial book. Further particulars from the office of the Technical Museum, Vienna, I. Ebendorferstrasse 6.

PHOTOMETRIC UNITS AND NOMENCLATURE.

Owing to pressure on our space during the last few months we have been unable to deal adequately with an article on this subject by Dr. E. B. Rosa, which appeared a short time ago in the "Bulletin" of the Bureau of Standards. In view, however, of the recent contributions to the subject by Mr. A. P. Trotter and Mr. Haydn Harrison in our columns, the following summary of Dr. Rosa's article should prove of interest to our readers.

In an introduction to the article, Dr. Rosa mentions that the subject of photometric units and nomenclature received a notable impulse by the Paper of Blondel, presented to the Geneva Congress of 1896. Since that time various modifications in the proposals there made have been put forward, and the units and nomenclature there proposed have come into use to a greater or less degree. There has, however, been a tendency to recognise as few separate photometric quantities as possible, and some of them have been employed rather loosely in more than one sense. This is partly, at least, due to a lack of clearness in the perception of the physical relation of the various photometric quantities. The Illuminating Engineering Society appointed a committee* on this subject something over a year ago, and it was due to my membership of this committee that I was led to give the matter careful attention. Some of the names are here used in a different sense from what has been usual, and slight changes have been made in some of the symbols. These are in the interest of a more systematic arrangement and also of international uniformity.

Dr. Rosa then proceeds to discuss the mathematical and physical relationships of the various photometric quantities, and finally summarises the photometric relations as follows:—

Luminous flux or light, as the term is used in photometry, is the usual physical stimulus which excites vision. It is propagated by means of the vibratory motion in the ether, and the frequency of the vibrations or the combination of frequencies present in any given case determines the colour. The total quantity of flux F flowing away from a monochromatic luminous source is proportional to the total radiant energy (per second) and to a stimulus coefficient, the latter being the luminous efficiency K_λ for the particular frequency or wave length of the given radiation. Thus the equations $F=K_\lambda^{\prime}W$ and $K_\lambda=F_\lambda/W_\lambda^{\prime}$ express the luminous flux as the power W multiplied by the luminous efficiency K_λ, and if the flux is expressed in lumens and the power in watts, the luminous efficiency is the number of lumens per watt of radiation of the wave length λ. For white or chromatic light K will have a value depending on the distribution of the energy in the spectrum. It is a maximum in the yellow-green region and falls off rapidly in either direction, reaching zero at the limits of the visible spectrum. The luminous efficiency of most light sources is greatly reduced by the amount of radiation outside the visible spectrum, chiefly of longer wave length than that of visible radiation, and the total efficiency of such a source $K=F/W$ is the quotient of the total luminous flux divided by the total radiant power.

For the purposes of definition and of expressing the mathematical relations involved in photometry, it is permissible to confine ourselves to monochromatic light and to consider K a constant, although it does in fact vary somewhat with the magnitude of the flux density. We also assume that all surfaces are perfectly diffusing and obey the cosine law and that there is no absorption in the atmosphere.

The intensity of a point source or uniform luminous sphere is measured by the luminous flux flowing through a unit solid angle whose apex is the given point or centre of the given sphere. Thus from a source of intensity I, light is flowing away at a rate of I lumens per unit solid angle, or a total of $4\pi I$ lumens for the point source or uniform sphere. If the source is not uniform and light is flowing away at unequal rates in different directions, the intensity I in any direction is equal to the flux dF in an elementary solid angle $d\omega$ taken in the given direction. Thus, $I=dF/d\omega$ is a general expression applying to all point sources whether radiating equally or unequally in different directions. If the unsymmetrical source is extended—as, for example, an incandescent lamp or a diffusing globe—the same holds true if the distance at which the measurements are made is sufficiently great so that the distribution of light is practically the same as from an unsymmetrical point source. For less distances than this the intensity is not a constant in a given direction, but varies with r. In this case the equivalent intensity at any point is equal to that of a point source which gives the same flux density, or lumens, per square centimetre at the point that the given source does. The mean spherical intensity I_s is the average value of the intensity and is equal to the total flux F divided by 4π.

The total flux from a given extended source is therefore a constant independent of distance, as is also the mean spherical intensity I_s. The intensity I in a particular direction, however, in the case of extended sources other than spheres varies with the distance, but at relatively great distances the variation is inappreciable. Thus the luminous flux is the fundamental quantity. But while we define I as the flux per unit solid angle, or rate of flux with respect to solid angle, we determine I by comparison with a concrete standard. Thus photometric standards of intensity are standards of light flux, their values being expressed in candles.

If f is the spherical reduction factor with respect to any particular direction, and I is the intensity of a source in that direction, $I_s=fI$. For a unit disc—that is, a small circular disc of uniform brightness—the total flux is π times the normal intensity I_n, whereas the mean spherical reduction factor with respect to the normal is one-fourth. Hence, the total flux is $F=\pi I_1=4\pi I_n$, as for a sphere. In general, for any light source, $F_s=4\pi I_s=4\pi fI$, but for extended sources other than spheres, the value of f as well as I varies with the distance from the source for points relatively near the source.

The specific flux or flux density is the luminous flux per unit of area, or lumens per square centimetre. When the flux falls upon a material surface, we call the specific flux the illumination E. When we speak of the flux coming from a surface, whether it be a self-luminous source at high temperature or a reflecting or radiating surface at low temperature, we call the specific flux the specific radiation, or simply the radiation E′.

Thus the illumination is $E=\frac{F_i}{S}=\frac{dF_i}{dS}=\frac{I}{r^2}$; and the radiation E′ is $E'=\frac{F_r}{S}=\frac{dF_r}{dS}$, where F_i is the incident flux and F_r is the emitted or radiated flux. If m is the coefficient of diffuse reflection or transmission, $(1-m)$ being the absorption, $F_r=mF_i$ and $E'=mE$, where the radiation consists in the diffuse reflection or transmission of a portion of the incident flux or illumination.

The radiation or illumination when large may be expressed in lumens per square centimetre; when small in milli-lumens per square centimetre. The milli-lumen per square centimetre is nearly equivalent to the foot-candle.

The brightness b of a source is the intensity in candles per square centimetre of area taken normally. Thus $b=\frac{I}{S}=\frac{dI}{dS}=\frac{dQ}{dS}$. Brightness, or specific quantity, refers to the quantity of light per unit of area of a source, and is measured in candles per square centimetre. Brightness can refer equally to luminous sources of relatively high specific intensity or to reflecting and radiating sources of low intensities. The latter may be conveniently expressed in milli-lumens per square centimetre. Thus we may say a flame has a specific radiation of 10 lumens per square centimetre or a brightness of 0·8 candles per square centimetre; and a wall has a specific radiation of 10 milli-lumens per square centimetre, or a brightness of 0·8 milli-candles per square centimetre or of 8 candles per square metre.

The quantity Q is proportional to the total amount of light emitted by the source, and is equal to the surface integral of the brightness b. Thus, $Q=\int b dS$. The quantity for a small luminous circular disc of radius a and uniform brightness b is $Q=\pi a^2 b=I_n$. That is, the quantity is equal to the maximum intensity. In this case the whole surface is equally effective in producing the illumination on the test screen by which the intensity I_n is measured. But for an extended disc, the quantity and the normal intensity are not the same.

The total luminous flux is π times the quantity, and the mean hemispherical intensity is half the quantity.

In the case of a sphere of uniform brightness b, the quantity is $4\pi a^2 b$; the intensity $\pi a^2 b$, or one-fourth the quantity. In other words, the total radiation from the sphere is four times as great as from a unit disc of the same normal intensity. The total luminous flux delivered in a given time—that is, the time integral of the luminous flux—may be expressed in lumen-seconds or lumen-hours, according to circumstances. Thus, putting L for the total lighting in the time T, $L=FT$ or $=\int F dT$ if F is variable, where F is in lumens and the time is expressed in the most convenient unit. The flash of a firefly may be expressed in lumen-seconds; the total lighting per gramme of an illuminant, or the total lighting given during the life of an incandescent lamp, is better expressed in lumen-hours.

Since flux of light may also be expressed in spherical candles (4π times the lumens), we may also express the time integral or total lighting in terms of spherical candles and hours. Thus $L=I_s T=\int I dT$ if the spherical candle-power is a variable with respect to T, the value of L being here given in candle-hours.

The photometric quantities employed in the preceding discussion

* The committee consists of Dr. C. H. Sharp (chairman), Prof. A. E. Kennelly, Prof. E. L. Nichols, Prof. A. Blondel, and the writer.

Digitized by Google

are shown in the following table, together with the units in which they are expressed.

Photometric magnitude.	Symbol.	Unit.
1. Intensity of light	I	Candle.
2. Luminous flux	F	Lumen.
3. Illumination	E	$\frac{\text{Lumens}}{\text{cm}^2}$ or $\frac{\text{milli-lumens}}{\text{cm}^2}$.
4. Radiation	E′	Lux = metre-candle.
5. Brightness	b	Candles/cm^2.
6. Quantity	Q	Candles.
7. Lighting	L	Lumen-hours.

The symbol F has been employed for the flux (as originally proposed by Hospitalier) instead of Φ, for the following reasons: (1) Φ is the only Greek letter in the series, and it is more consistent to use a Latin letter; F is the initial letter of the word flux. (2) The letter Φ is more or less unfamiliar to many illuminating engineers and also to many printing offices, and it is often confused with the small letter ϕ, which is used for an angle.

The symbol E′ is used for radiation instead of R (as proposed by Hospitalier) because it is so closely related to the illumination, and because the letter R is employed for the distance from the source. Blondel and others proposed to employ the same letter, E, for illumination and radiation, but that gives rise to confusion. On the other hand, E′ gives sufficient distinction and at the same time recalls their close connection. The letter b is used for brightness instead of i for specific intensity because i is used for the angle of emission, and specific intensity is a less desirable name. The quantity is a specific intensity strictly only for small plane areas, not for small spheres or large sources of any form. Quantity of light, Q, is here used as the surface integral of b instead of the time integral of F. It is analogous to quantity of electricity in electrostatics and is more properly employed in the sense here used than with the other meaning. The term lighting, for flux times time, is used in harmony with the usage in France and Germany.

PARLIAMENTARY INTELLIGENCE.

TELEPHONE TRANSFER BILL.

On Friday the House of Commons went into Committee to consider this Bill.

On clause 2 Mr. PETO moved the insertion of words to make it clear that a portion of the £4,000,000 should be devoted to the development of the telephonic system "in rural as well as in urban areas."

Capt. NORTON maintained that there was no object in inserting these words, because the clause would carry out the object which the hon. member had in view.

The amendment was negatived.

On clause 5, Mr. J. F. HOPE said there were still outstanding some points with regard to the staff, and if the further consideration of the bill were postponed to the autumn session an opportunity would be afforded for settling them.

Mr. JOYNSON HICKS said the greater part of the claims of the staff had not been satisfactorily met. There was the question of the pension rights. No telephone employee should be in a worse position under the Post Office.

Mr. H. SAMUEL opposed the motion to report progress and said that of the 18,000 persons now in the National Telephone Company's service only 2,000 were on the pension fund. The State was taking over the whole of the 18,000 and putting 12,000 of them on the pension fund, so that 10,000 of the Company's servants would receive pension rights for the first time and without paying the 2½ per cent. deduction which they paid now. The 300 or 400 men referred to by Mr. Joynson-Hicks were for the most part men engaged in constructional work, and would not be pensionable even if they had been from the first in the service of the Post Office. The Post Office at the present employed 5,000 men of that class, and it would be impossible to give pensions to the new comers and deny them to old servants of the Post Office in the same class. He undertook to postpone the consideration of clause 5 until next week, and in the meantime to have a consultation with the Treasury with a view of reaching an understanding on the question that had been raised.

The consideration of clause 5 was, therefore, postponed.

On clause 6, which contains temporary provisions as to the transfer,

On the motion of Mr. SAMUEL several amendments, designed to bring the terms of the clause into conformity with the agreement which he had made with the National Telephone Co., were also agreed to. He proposed to omit sub-sections 1, 2 and 4, which were unnecessary, and to substitute for the words "the appointed day" a fixed date—Dec. 31, 1911. New clauses providing for an audit of the accounts under the Bill and under the Telegraph Act, 1892, the Telegraph (Money) Act, 1896, the Telegraph (Money) Act, 1898, the Telegraph Act, 1899, the Telegraph (Money) Act, 1904, and the Telegraph (Money) Act, 1907, and making provision as to gratuities to transferred officers were agreed to.

On Wednesday the House of Commons again went into Committee on this Bill.

Mr. H. SAMUEL moved a new clause dealing with provisions as to the superannuation of transferred officers, in substitution of Clause 5. He stated that those members of the company's construction staff who were now pensionable, and also the contract officers pensionable, would be placed on the Post Office establishment, and those of them who were not pensionable would have equal chances with Post Office employés to be placed on the establishment.

The clause was read a second time and added to the bill, clause 5 being struck out.

The bill was then reported, as amended, to the House.

Pacific Cable Bill.—In the House of Commons on Wednesday this Bill passed through the Committee stage and it will be read a third time to-day, Friday.

LEGAL INTELLIGENCE.

Workmen's Compensation.

At Burnley County Court on 11th inst., John Clague and Eliza Crossley sued for compensation in respect of the death of John Clague, junr., overhead wireman, who was fatally injured whilst in the employ of Burnley Corporation. On June 18 deceased was repairing wires in Church-street when a portable furnace burst, and the petroleum set fire to his clothing. He sustained injuries which resulted in his death. Deceased's father was totally dependent on his earnings. The case was adjourned, but it was agreed the father should receive 8s. per week and £10 down.

1911 SPECIFICATIONS.

6,627 SIEMENS BROS. & CO. (Siemens & Halske Akt.-Ges.) Electric block signalling systems.
6,833 BARRET & GAIFFE. X-ray bulbs and tubes. (7/9/10.)
7,198 MUNRO & RAIL-LESS ELECTRIC TRACTION CO. Trolley bases for electric traction systems. (Divided application on 11,157/10. May 5.)
8,150 ALLGEMEINE ELEKTRICITATS GES. Regulating the voltage of direct-current machines running at variable speeds. (1/4/10.)

Digitized by Google

ELECTRIC WINDERS.

In our second Mining Issue we gave particulars of a large number of electric winders. Unfortunately, details from the A.E.G. came to hand too late for inclusion, but as we desire the information to be as complete as possible we think it well to publish the following supplementary list of A.E.G. installations. We also add some details of winders supplied by the Ateliers de Constructions Electriques de Charleroi. The whole will show what great progress has been made.

Owners.	Name of pit.	Depth. m.	Net load. kg.	Max. speed in metres per sec.	Motor H.P.	Supply. System.	Supply. Voltage.	Frequency.	System of Driving.
WINDERS SUPPLIED BY THE ALLGEMEINE ELEKTRIZITÄTS GESELLSCHAFT.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Ashton-under-Lyne.—The salary of the assistant electrical engineer (Mr. W. A. Wales) has been increased by £25 per annum.

Burnley.—The Rural Council have assented to the proposal of the Corporation to apply for a provisional electric lighting order for the parish of Reedley Hallows.

Carlton Hotel Fire.—Mr. H. B. Renwick, chairman of the Electric Supply Publicity Committee, Moorgate-court, London, E.C., has written to the press pointing out that the statement that the recent fire at the Carlton Hotel was caused by the fusing of an electric wire is without foundation. The Electric Supply Company, who supplied the hotel, had made a thorough investigation, and gave full assurance that there was no evidence whatever to connect the fire with any electrical source. Further, the official London County Council report of the London Fire Brigade gives the supposed cause of fire as "unknown."

Clydebank.—The Tramway Committee have been authorised to make a definite offer to Glasgow Corporation for the completion of the tramway bridges, but the Corporation are to be asked to give an undertaking for the proper working of the bridges and the completion of the tramway undertaking.

Ealing.—At last week's Council meeting the Mayor (Councillor Roose-Francis) congratulated the borough electrical engineer (Mr. J. D. Knight) and the Electricity Committee on the fact that the profit on the electricity supply department for the past year was £1,700.

The Committee recommended the purchase of 35, Bond-street for £1,200 and to authorise the expenditure of £500 in necessary alterations, heating and lighting, the £1,700 to be provided out of reserve.

Ald. PEAL, moving the adoption of the report, said the electricity staff was crowded out and the heating of the offices was unsatisfactory. New offices were, therefore, necessary.

The matter was, however, deferred for a month.

Electric Lamps in Mines.—An inquest was held last week at Brynceithein (Glam.) on two miners named Rogers and Davies who were killed on 29th ult.

Evidence was given to show that deceased were found in a place known as "Waller's Top Hole," which was being driven for connecting to the tip-airway.

A witness named Evans said he and another man named Lewis had charged a hole when working in the pit but he was rendered unconscious by an escape of gas. When he recovered consciousness he remembered someone pulling him down from the top hole to the bottom. The hole he had driven was about 2 in. wide, and the thickness of the coal about 2 ft. 6 in. The coal above that must have been much thinner, and directly Lewis touched it it scattered. It was commonly known that since a fall occurred three or four weeks ago there was gas in the place they were working towards, and the place had been stopped. Everything went on all right until the fall occurred, and then the company concentrated their efforts on getting the air round by the upper connection. It was with that object that they were working at the stump of coal. They worked with electric lamps, and the manager left his safety lamp 30 or 35 yd. away.

Col. PEARSON (mines inspector): You were given electric lamps to work in a place which contained gas?—Yes, sir.

Is that regular?—No.

Do you know it is in contravention of General Rule No. 1 that any man shall work in any place where there is an accumulation of gas?—No answer.

You did it on the instruction of the manager?—Yes. After plugging the hole there was no gas in the place.

Col. PEARSON: If you had had a safety lamp it would have indicated danger. Was it not a wrong thing to put electric lamps into your hands?

Mr. KENSHOLE (for the company) said he could not agree. There was nothing in the rules to prevent the use of electric lamps.

Col. PEARSON said the rules specifically stated that safety lamps should be used where there was gas.

Mr. KENSHOLE contested the point whether an electric lamp was not a safety lamp within the meaning of the Act. There were many collieries where electric lamps were in general use.

The CORONER (to witness): What would have happened if you had had safety lamps?—It might have been that the whole colliery would have been blown up.

Would you have had time to get out after the burst of gas if you had had a safety lamp?—No.

After hearing the evidence, the jury returned a verdict of "Misadventure," and found that deceased had died through suffocation. They added that if the deceased men had been using safety lamps at the time the deaths would not have occurred.

Garvagh (Ireland).—A meeting of ratepayers is to be called to consider a proposal to adopt public electric lighting. Electric current would be supplied by a local mill owner, Mr. Samuel Stewart.

Glasgow.—The motor men and conductors of the Corporation tramways went out on strike on Saturday morning last. A limited service of cars was, however, run until Tuesday, when the strike collapsed and the full service was resumed.

Harbour Lighting.—Irvine Harbour Trust last week decided to engage an electrical engineer to prepare a report on the probable cost of lighting the harbour by electricity and what further use could be made of electricity with a view to cheapening cost in any other branch of the harbour plant.

Hessle.—The Urban Council have decided to purchase electricity in bulk from Hull Corporation. It is estimated that Hessle will take about 70,000 units at the outset at 2d. per unit.

Inquest.—An inquest was held on Tuesday at Middlesbrough on a caulker named Best, employed at Smith's Dock.

Evidence was given that an electric crane runs along the dock jetty and that the power cables were placed in a conduit. Best, whilst walking along the jetty, dropped a packet of white lead which fell into the conduit, and in trying to recover it he touched the live wires and was killed.

A verdict of accidental death was returned.

Light Railways.—The Board of Trade have confirmed the County of Hertford (Cheshunt) Light Railways Order, 1911, authorising the abandonment of part of the railway authorised by the County of Hertford Light Railways Order, 1906, and reviving the powers of the County Council in respect of the remainder of that railway, and for other purposes.

Lytham.—The Council have been notified that a company proposes to apply for a provisional electric lighting order.

Morecambe.—The Board of Trade have sanctioned a loan of £4,617 for doubling the tramway track to Bore and £800 for additional cars.

Osram Lamp Patent Litigation.—The Osram Lamp Works (Ltd.) are issuing a notice relating to the action recently brought by them against the British Tungsten Lamp Co. and another for infringement of their letters patent, in which they state that an order was, by consent, made on 26th ult., whereby it was (among other things) ordered that:—

The defendants, their servants, agents and workmen be restrained during the continuance of certain letters patent from importing into and from making, selling, offering for sale, supplying and using any illuminating bodies, or electric lamps containing illuminating bodies, made according to or in manner described and claimed in the specification of such letters patent, or according to or in manner only colourably differing therefrom, and generally from infringing the rights of plaintiffs under the said letters patent, and that defendants do pay to plaintiffs the sum agreed for damages sustained by plaintiffs or to be sustained by reason of the infringement of the said letters patent by defendants by manufacture and sale prior to the date thereof of lamps and filaments and the sale of the lamps then in stock or by reason of the user of such lamps and filaments, and that defendants do pay to plaintiffs their taxed costs of the said action.

Railless Trolley Traction.—Dundee Tramways Committee have instructed the manager (Mr. Fisher) and the city electrical engineer (Mr. H. Richardson) to prepare plans, &c., for introducing the railless trolley system of traction on the Clepington-road route.

Dewsbury Council have been in negotiation for some time with the Yorkshire (Woollen District) Electric Tramways (Ltd.) in regard to certain proposed extensions of the tramway system.

The local lines are held by the company on a lease from the Council for 28 years and extensions must be matter for negotiation. The Corporation must provide the capital expenditure. If the company fails to meet the wishes of the Corporation for a new line after six months' notice, the Corporation may themselves make and work the extension line. Such notice has been given in regard to a tramway to Westboro' and it will expire next month. In the meantime the company have replied that after giving the proposal careful consideration they are unable to see that the capital expenditure necessary would be justified for many years to come, but they offer as an alternative to prepare estimates for undertaking the rail-less trolley system on the route. The Parliamentary and Tramways Committee have considered the matter and instructed the borough surveyor to prepare plans of alternative routes to Westboro'.

Digitized by Google

On Aug. 1 they inspected the Leeds rail-less trolley system, but they report that they are not favourably impressed with its suitability for the steep gradients to be encountered on the Westboro' route.

St. Anne's-on-Sea.– There are over 1,000 consumers now connected to the electricity supply mains, an increase of about 100 consumers in 12 months.

Stalybridge, Hyde, &c., Tramways.—It has been decided to reconstruct the Ditcheroft Hill tramway route.

Walsall.—The Assistant Electrical Engineer has been instructed to make good the damage caused by the recent fire at Butts-road sub-station by altering the existing switchboards so as to bring them more up to date, at a cost of £125.

A coal elevator is to be provided for the new boiler at a cost of £120. The Tramways manager has been instructed to have one of the cars fitted with speed indicators, and to arrange for each motorman in turn to handle the cars so as to obtain some training in the judgment of various speeds.

Wishaw.—At Monday's meeting of the Council it was reported that there was a deficit of £81 on the past year's working of the electricity department, against £417 in 1910.

Yarmouth.—Electric lighting is to be adopted at Southtown. Electric current is to be taken from the trolley wires and the lamps are to be hung from the posts on anti-vibration holders.

COLONIAL AND FOREIGN NOTES.

Argentina.– The concessionaires of the proposed electric tramway from Buenos Ayres to the Tigre have applied to the La Plata Government for permission to extend the original route.

Australasia.—An Act of the New South Wales Legislature of December, 1910, authorises the construction of an electric tramway from Darley-road, Randwick, to Coogee, at an estimated cost of £81,763.

Erskineville Council has contracted with Sydney (N.S.W.) City Council for the supply of electricity for lighting and power. The Erskineville Council are to pay £3 per annum for 40 c.p. incandescent lamps, £3. 7s. 6d. for 50 c.p., £3. 17s. for 60 c.p., and £6 for 100 c.p. lamps. For arc lamps of 1,500 c.p. they are to pay £16, 2,000 c.p. £19, and for 2,500 c.p. lamps £22.

Waterloo (N.S.W.) Council have entered into a contract with Sydney City Council for lighting the municipality with electricity and supplying power to the factories in the district. The City Council now have the right of supplying electric light and power to Botany, North Botany, Alexandria and Waterloo. The other municipality in the division is Redfern, the Council of which has virtually agreed to accept the offer of the City Council to purchase their goodwill for £20,000.

The Federal Cabinet recently decided that provision should be made when calling for tenders for telephone switchboards to give makers of automatic boards an opportunity of competing, and the Postmaster-General was so far favourably impressed with the working of this device that, although tenders had already been invited with respect to a manually-operated switchboard for Perth, new tenders are to be called for either manual or automatic operation. The exchanges at Norwood and Unley (S. Aus.) and at Geelong (V.) also require new switchboards, and in these cases also tenders will be asked for both manual and automatic forms.

The poll of the Hawthorn (V.) ratepayers has resulted in a large majority in favour of the agreement with the City Council and Melbourne Electric Supply Co. for street lighting.

Christchurch (N.Z.) electric tramways made a net profit of £2,200 on their last year's working.

Preston (V.) Shire Council have adopted an electricity supply scheme prepared by Messrs. Lincolne & McDougall and estimated to cost £4,524.

In future specifications for copper wire for the railways and tramways of New South Wales the following paragraph is to be inserted :—" Other things being equal, preference will be given to tenderers offering to supply Australian copper wire, provided it complies with all the requirements of this specification." The Federal Postmaster-General has also agreed to insert this paragraph in his specification.

The Inverell (N.S.W.) municipal electricity works will commence the supply of current in September.

The ratepayers of the Mangaweka Rangitikei district (N.Z.) have approved a proposal to raise £10,000 for electricity supply and other new works.

Recently Alexandria Municipal Council entered into a 10 years' contract with Sydney City Council for the electric lighting of its thoroughfares and for the supply of electrical energy for private lighting and power.

Prahran and Malvern Tramways Trust have accepted a tender for the construction of the permanent way of the Dandenong road line.

The Royal Commission on the railway and tramway services of Melbourne and suburbs has taken further evidence.

Mr. JOHN CLAYTON, town clerk of Melbourne, advocated municipal in preference to Government control of the tramways, and compared the management of the Prahran-Malvern system with that of the St. Kilda-Brighton system controlled by the Railway department. He was also of opinion that the compensation due to the municipalities, if the Government should decide on State control, would be very large, the present working value of the capital invested in the tramways being £1,500,000. With regard to the distribution of profits between the municipalities, he advocated the car-mileage basis. He considered that a municipal management would be more likely to build new lines, and so relieve congestion in the central area, than would a Government control. A betterment rate for a tramway undertaking would prove impracticable. In some cases the tramway would take business from a small district to a larger but neighbouring one, so that a "worsement" rate was a proper complement to the other. He was in favour of extension to districts not now served in preference to the electrification immediately of the existing systems. Electrification in Melbourne would come in time, though in the principal streets of the city practically nothing could be gained. He did not think the advantages would warrant immediate electrification of the present system.

Mr. PERCY ROSLING, president of the Victorian Institute of Electrical Engineers, advocated the overhead electrical system on the grounds of economy in construction and facility of supervision and maintenance. The aesthetic objections to an overhead service did not appeal to him. He preferred the central to the span wire system; span wires were unsuitable to Melbourne streets on account of the great sag, due to the width of the streets. On the question of electrifying the suburban railways, he preferred direct-current to high-tension alternating current.

Mr. W. G. TOOP GOODMAN, chief engineer and general manager of the Adelaide tramways, prepared the following figures respecting the comparative cost of conduit, span-wire, and central-pole constructions: (a) Cost of constructing a conduit system for electric traction, including conduit, conductor rails, boarding, insulators and permanent way, with wood block paving, £21,000 per mile of single track. (The estimate included an average percentage for special work and 15 per cent. for engineering and contingencies); (b) Cost of permanent way, with tarred macadam surface and steel span-pole construction, £6,765 per mile of single track and £11,820 double track. For wood span-hole construction and permanent way, with plain macadam surface, he estimated the cost per mile of single track at £5,350, double track £9,730. (c) The cost of permanent way, with tarred macadam finish and steel centre-pole construction would be £11,480 double track. The cost of overhead construction would be: Steel span-pole construction (double track), £1,710 per mile; steel centre-pole construction (single or double track), £1,570 per mile; wood span-pole construction (single or double track), £960 per mile. He was of opinion that the present cable conduits would not be suitable for electric traction. In Adelaide the cost of maintenance of the overhead system was 1·18d. per car-mile, but the maintenance cost of a conduit system would be at least ½d. more, and that on an extensive system would run into very large figures. Eventually the superiority of electric traction would justify the conversion of the Melbourne system to electric, though it would take some years to do so. During the last three or four years great developments had taken place in the alternating-current system, and at present it was difficult to get figures that would enable him to draw a fair comparison between direct and alternating current. For purely suburban traffic the balance was in favour of the direct current if the area be limited, but if an unlimited area be taken with lines extending 40 or 50 miles out of Melbourne, it was an open question. Electrification would make it more than ever necessary to re-duplicate the railways, especially that to Caulfield, though that would have to be done whether electrification were adopted or not; and it would be better to re-grade and re-duplicate at the same time. He strongly advocated electrification, and added that, service for service, electric traction was dearer than steam. But with electric traction the quicker service and increased facilities would result in an increase of traffic that would more than compensate for the extra cost of operation.

Mr. Walter Karplus, chief electrical engineer of Siemens Bros. Dynamo Works, stated that the fact that 90 per cent. of the electric tramways of the world were operated by the overhead system was evidence that that method of traction was considered the best available. The most important considerations that had operated against the adoption of the conduit system were its initial cost, its maintenance cost and its working expenses. If anything went wrong, the time occupied in setting things right was greater. He would not recommend the conduit system even for the busiest streets in the city. He advocated the overhead system with standards on each side of the streets in the city, but centre poles outside the city wherever the streets were wide enough, and side poles with projecting brackets in the narrower streets.

A sub-committee of the Victorian Institute of Electrical Engineers has been appointed to consider the question of licensing electrical wiremen.

Temora (N.S.W.) is to have electricity supply works at a cost of £[illegible].

Birchip (V.) electricity works were inaugurated on July 11.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

Digitized by Google

Nugawading (V.) Shire Council have instructed Mr. McDougall (of Lincolne & McDougall) to prepare a scheme of electricity supply for the district.

Negotiations are proceeding between Hobart City Council and the local tramway company for the purchase of the company's undertaking. The company have agreed to sell for £250,000, but the Council only offer £150,000.

Customs Decisions.—Under the Netherlands customs tariffs automatic reversing switches for electric lifts pay 5 per cent. ad valorem duty (as "iron wares"), but slates for use in the manufacture of switchboards and insulators are admitted free.

Japan.—The "Osaka Asahi" says the manufacture of electric wire appears to have good prospects in Japan, and the demand is now not less than £1,400,000 per annum.

Last year the output of wire by the Furukawa Mining Firm (the proprietors of the Ashio copper mine) was twice as large as that for the preceding year. The annual production of copper in Japan is about 120,000,000 lb., of which 24 per cent. is consumed for electrical work, and according to an authority, the total amount of capital invested in the wire making industry is about £1,000,000. The value of the annual production of uncovered wire in Japan is about £750,000, that of wire covered with cotton about £530,000, and that of wire covered with rubber about £300,000. Besides these, telegraph cables and galvanised wire are produced to the value of about £130,000 a year. Of rubber-covered wire the Japanese supply 70 per cent. and foreign firms 30 per cent. of the demand; galvanised wire about equally. Foreign firms still supply 80 per cent. of telegraph cable requirements. Electric wires and cable are still imported into Japan to the value of over £300,000 a year. Japanese makers cannot yet compete successfully with foreign firms in price, but have made progress in skill and workmanship. The demand for underground and short lengths of submarine telegraph cables and military telegraph wires is said to be met from local sources, and the Japanese Government has increased the duty on electric wires about three-fold to protect the Japanese industry.

The Yokohama Electric Wire Co. is about to open a new factory for insulated wires, the capital (£60,000) to be jointly contributed by that company and the Furukawa Mining Firm. A scheme is also on foot in Tokyo to set up works for the manufacture of electrical machinery, the concern to be a branch of the A.E.G., of Berlin. Other enterprises of a similar nature are in contemplation, largely with a view to meet the increasing demand of the Russian littoral, Korea, India and Australia.

Paris Telephone Service.—The text of a decree, dated July 29, has been issued, authorising the expenditure of 11,667,700 frs. (about £466,708) for improving and extending the Paris telephone service.

Russia.—Mr. H. Cooke, H.M. Commercial Attaché, reports that the Imperial assent has been granted to a proposal by Mr. Ushkoff to form a company for the construction, without guarantees from the Government, of an electric railway in the Crimea from Sevastopol, via Yalta, to Alushta, with a branch to Balaklava. The total length of line will be about 84 miles. A printed pamphlet (in English) can be seen at 73, Basinghall-street, London, E.C.

In a consular report on the trade of Kharkov, Mr. Vice-Consul Blakey states that in the heavy engineering, and particularly in electrical engineering, the Germans have shown more enterprise than the British.

The Germans have branch offices under their own management with experienced engineers at the head, a staff of suitable men and branch factories in Russia to supply parts of contracts that cannot profitably be imported. They have thus established a reliable trade, while the British remain dependent upon the good-will of their agents. In the trade in machine tools, agricultural machinery and portable engines German firms have a large share. The trade in electrical machinery and in semi-portable engines is entirely in their hands. In steam engines they do a good trade and hold a high reputation. The hold a large proportion of the imports of oil, gas and Diesel motors. In mining machinery and coal-washing plants, and in transporters and in brick-making machines they also lead. Mr. Blakey is assured that the British manufacturer could well compete in everything but electrical engineering if he were as well served by a sales department in Russia as his German rival.

South Africa.—At the Klerksdorp municipal electricity works a gas-driven set was recently installed, including a 78 B.H.P. Hornsby twin-cylinder gas engine (with suction gas-producing plant) coupled to an E.C.C. dynamo.

Johannesburg Council have adopted a revised tariff for domestic electric lighting, by which dwelling houses are to be rated on a basis of six units per room per month at 6d. per unit, and the balance at 1½d. per unit. As an alternative, an extra meter with time switch can be fixed at the consumer's cost, and energy consumed between 5 p. m. and 11 p.m. charge at 6d. per unit, and during the remaining hours at 1½d.

Ladysmith Corporation have arranged to supply electrical energy to the South African Railway at Ladysmith (O.F.S.) Junction and the new yard, with a guaranteed consumption of 168,000 units per annum.

Spain.—Don Garcia de Pruneda has applied to the Ministry of Fomento for a concession for constructing and working an electric tramway in Madrid.

The Société anon. des Tramways de Barcelone has applied to the Ministry of Fomento for a concession for the construction of an electric tramway in Barcelona.

Telegraphs in the United States.—An interesting open letter addressed by the Postal Telegraph Cable Co. of New York, to the Attorney-General of Texas, is in circulation, and shows the keen competition, which is the leading feature of telegraphic matters on the other side. The open letter to which we refer deals with the efforts that have been made by the Postal Telegraph Cable Co. of New York during the past 25 years, the competition which these efforts have invited, and a general review of the situation as it stands to-day.

Venezuela.—The British Vice-Consul at Maracaibo reports that there are openings at present for electric tramways in the town of Maracaibo. Various offers have been presented to the Municipality but none has been approved so far.

Wireless Telegraph Note.—According to a note from America, wireless telegraphy is entering into keen competition with the telephone in certain large business houses in New York and Philadelphia. The note concludes: "The ease and rapidity of wireless communication suggested the use of the stations as a substitute for the telephone, with the result that the latter has been completely ousted." We do no more than record the statement published.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Aberdeen.—The revenue of the tramways department for the year ended May 31 was the highest in the history of the undertaking—£73,470, against £71,121 in 1910.

In his report the general manager (Mr. R. S. Pilcher) states that the revenue had been practically stationary for the previous four years. The increase is attributed to the weather, the winter having been exceptionally mild, and there being practically no snow or severe frost. The working expenses were £39,674. 17s. 6d., a decrease of £777.

The total revenue was £73,470, including £72,417 traffic receipts, and the total working expenses were £39,675, leaving a gross profit of £33,795. After paying interest and sinking fund, and providing for depreciation, &c., £17,459 was carried to the renewal account. The capital expenditure is £315,395. 18,027,584 passengers were carried, against 17,156,050, and 1,619,503 car-miles run, against 1,585,137.

Beckenham.—The accounts of the electric supply department for the year ended March 31 show total nett capital expenditure of £94,234.

The amount borrowed for "free" wiring was £27,000, of which £14,959 is outstanding, making the total indebtedness £109,192, and the annual repayment of principal and interest being £10,570. The total receipts were £10,925 for private lighting, £340 for public lighting, £2,277 for traction, and £2,209 meter rents. The total expenses were £7,066, but after meeting charges there was a nett deficit of £1,062, but deducting sale of "free" wiring installations and adding previous loss (£251) the total deficit was £1,094.

The Chairman of the Electricity Committee (Mr. Sjollema), who moved the adoption of the accounts at the last Council meeting, referred to the excellent work done by the showroom in increasing the popularity of electricity, and thought they ought to take the profit made on the fittings sold.

Glasgow.—In presenting the accounts of the electricity department for the year ended May, Bailie Willock stated at the meeting of the Corporation last week that the depression from which the department had suffered, in common with other industrial concerns during the past three years, was disappearing.

The revenue account showed a substantial increase and the cost of working had improved. After depreciation had been deducted there was a net increase in capital expenditure of only £36,281, half due to extensions of mains. Revenue had increased from £245,959 to £260,526, an increase of £14,567, which had been derived largely from power consumers. The use of electricity for power had undoubtedly conduced to social welfare. Not only did it ensure a purer atmosphere in works and factories, but in other ways it increased the efficiency of the workers, and by bettering their working conditions improved the quality of their work. There had been practically no increase in public lighting during the year. Although 5,826,000 more units had been generated, the coal bill had only gone up £1,231, and that was wholly due, not to the increased units, but to the extra 9d. per ton paid for coal. The saving in coal consumed during the year was equivalent to about 15,000 tons, or a money saving of £6,000. The other items in the cost of generating had fallen ¼d. per unit sold, or a total saving of £2,500. Those were remarkable figures, and the engineers and general staff of the department were to be congratulated on the keen interest and the scientific intelligence which they brought to bear on their work. No other similar undertaking in the kingdom had shown such gratifying figures in any one year. The cost of distribution showed a slight increase, £1,647 having been spent on a thorough

Digitized by Google

overhaul of mains, cables and meters. Repairs of public lamps and management expenses had decreased, while taxes and assessments show an increase of £1,008. The statutory and other obligations in the shape of interest, sinking fund and depreciation showed an increase of £3,967, but relatively to the output there was really a decrease of ⅛d. per unit. The average price received during the past year had been just over 1¼d. per unit, and the cost of production had been just under 1¼d. per unit. The difference between the two was a surplus of £6,680 on the year's operations, and that sum the Committee had recommended to be carried to reserve. With the reduced price at which coal for the current year had been purchased, with an increase in consumption from lighting consumers, and the economies which the Committee had always an eye to, it was confidently anticipated that next year it would be possible to make a reduction in the rates to certain classes of consumers, although, with present prices for energy and the improved efficiency of incandescent and arc lamps, electricity was as cheap an illuminant as was available, while for power, both to large and small consumers, it was unequalled.

The accounts were approved.

Hove.—The accounts of the Aldrington electricity undertaking for the year ended March 31 show total receipts of £951 and expenses £598, leaving a gross profit of £353.

After meeting loan charges there was an adverse balance of £207 against a debit balance last year of £404. The purchase of electricity had cost £407, and the sale had realised £825.

Ilford.—The accounts of the electricity department of the Urban Council for the year ended March 31 have been issued.

The capital expenditure is £182,523, against £181,326. The total revenue was £31,805 (including £18,893 from consumers, £4,669 from tramways department, £7,206 from public lighting, and miscellaneous receipts £1,037), against £29,747 in 1909-10. The gross profit was £13,969 (£12,866), or 7·78 (7·42) per cent. on average capital. After paying interest (£6,117, against £5,754) and sinking fund (£6,452, against £5,543), there was a nett profit of £1,400, against £1,569. The number of units sold was 3,299,927 (1,225,658 private lighting, 531,842 power and heat, 546,290 public lighting and 996,137 traction), against 3,152,591 in 1909-10. The average price obtained was 2·02d. (against 2d.) per unit. There are 3,863 (3,543) consumers, the maximum load was 1,809 kw. (1,665 kw.), the load factor was 20·82 (21·61) per cent., and the units sold per consumer for private lighting were 455 (438). The cost of coal was 0·46d. (0·48d.) per unit, and the total costs were 1·02d., against 1·03d. per unit.

Nelson.—The accounts of the electricity supply and light railways departments for the year ended March 31 have been issued.

The income of the electricity department was £10,665, including £4,346 from private lighting supplies, £441 power and heating, £392 bulk supplies and £4,810 traction. The expenses were £5,181 and after paying interest and sinking fund instalment (£4,564) there was a net profit of £922. The total capital expended is £74,878, increase £177 over 1910. 1,062,176 units were generated and 920,456 units sold. The equivalent of 37,030 8 c.p. lamps is connected, against 34,500 8 c.p. and the horse-power of motors connected is 345 against 310.

The light railways carried 2,118,878 passengers, against 2,001,538, and 203,708 car-miles ran, against 200,115. After paying all expenses, including interest and sinking fund there was a deficit of £784 against an estimated loss of £1,146.

Salford.—The accounts and annual report of the general manager of the tramways department for the year ended March 31 have been issued.

The total length of lines owned by the Corporation is 36¾ miles, but 38¼ miles are also operated on lease, &c. The total income was £242,862, including £242,796 (10·004d. per car-mile) traffic receipts. The working expenses were £155,585, leaving a gross profit of £87,277. Interest and redemption of loans, &c., required £46,633, rents of leased lines came to £26,598, depreciation and renewals fund to £692 and after paying £185 for repairs, &c., of Bank-street cottages the net profit was £18,750. The passengers carried numbered 46,659,553, an increase of 718,778 and the car-miles run 5,824,474, an increase of 177,046. 9,301,713 units of electrical energy were used, or 1·66 units per car-mile. The gross capital expenditure is £721,338.

Watford.—The accounts of the electricity department for the year ended March 31 show gross capital expended £99,230, an increase of £3,807 during the year, but the net capital expended is £74,718.

The revenue was £13,791, including £9,033 nett from the sale of current by meter and £4,598 from public lighting. The total expenditure was £6,296, leaving a gross profit of £7,495. Interest on mortgage debentures absorbed £2,602, and instalments of principal £4,103, leaving a net profit of £791. 1,142,546 units were sold (789,361 for private lighting and power and 353,185 for public lighting) and the total maximum supply demanded was 760 kw.

In the report of the engineer and manager (Mr. F. W. Purse) it is pointed out that the total revenue increased by £1,145, while the working expenses increased only by £230; the capital charges increased by £398 and the net profit by £517. The temporary depression occasioned by the metal filament lamps had been overcome and there was every reason to expect that the future progress would be even greater than during the past year. The coal (0·5d.), works (0·88d.) and total costs per unit (1·32d.) were the lowest on record. The number of new consumers was 199 (against 143), equivalent to 8,515 32-watt lamps; the total consumers were 1,092 equivalent to 63,833 32-watt lamps.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

The WESTMINSTER ELECTRIC SUPPLY CORPORATION invite tenders for supply, delivery and erection at their Davies-street station of battery boosters and switchboards. Copies of specification, with drawing and general conditions can be obtained from the Secretary of the Corporation, Eccleston-place, Belgravia, S.W., to whom tenders should be sent by 10 a.m. of Sept. 12. Specification can be seen at (but not obtained from) the offices of the consulting engineers (Messrs. Kennedy and Jenkin), 17, Victoria-street, Westminster, S.W. See also an advertisement.

Tenders are invited (up to Oct. 3) for the supply of 42 miles of telephone cable to the Postmaster-General's department in VICTORIA. Tender forms, &c., from the Commonwealth offices, 72, Victoria-street, London, S.W. See an advertisement.

CLEETHORPES-WITH-THRUNSCOE Urban District Council invite tenders for the supply, delivery and laying down of a system of vulcanised bitumen distribution and feeder cables on the low-pressure three-wire d.c. system. Specification, conditions of contract and form of tender from the clerk of the Council, Mr. B. Greaves, Council offices, Cleethorpes, to whom tenders must be sent by noon of Saturday, Sept. 2. Specifications and general conditions of contract may be seen at the offices of the consulting engineers, Messrs. Vesey Brown & Hall, Milburn House, Newcastle-on-Tyne.

The Council of the County Borough of WEST HAM invite tenders for (*a*) water tube boilers, (*b*) coal handling and discharging plant, (*c*) 5,000 kw. turbo-alternator, with condensing plant, (*d*) river service pipe-work, (*e*) centrifugal pumps, (*f*) 750 kw. converter (two-phase to d.c.). Specification, form of tender, &c., from Mr. H. H. Couzens, engineer and manager, 84, Romford-road, Stratford. Tenders to the town clerk, Mr. Fred E. Hilleary, Town Hall, Stratford, E., by 10 a.m. Aug. 31.

Tenders will be received until noon Monday, Sept., 18 for the supply of Swedish, Norwegian, Finland or Russian red fir telegraph poles, for the GENERAL POST OFFICE. Forms of tender from the Controller of Stores, Mr. G. Morgan, Stores Department, G.P.O., 17 and 19, Bedford-street, London, W.C.

IPSWICH Corporation want tenders by Aug. 24 for one year's supply of paper-insulated underground cables. Specification from Mr. F. Ayton, Electricity Works, Constantine-road, Ipswich.

WEST HAM Guardians invite tenders for 12 months' electrical stores. Tenders to chairman by 11 a.m. Aug. 31.

Tenders are invited up to Sept. 26 for the supply of telephone material and 30 miles of telephone cable to the Postmaster-General's Department in VICTORIA. Specifications, forms of tender, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W., See also an advertisement.

Tenders are invited up to Aug. 30 for supply of porcelain insulators, copper wire, sleeves, &c., to the Postmaster-General's department in SOUTH AUSTRALIA; and up to Sept. 5 for the supply of (*a*) 10,000 protectors and (*b*) sundries to the Postmaster-General's Department in VICTORIA. Tender forms and specifications at the Commonwealth Office, 72, Victoria-street, London, S.W.

The Metropolitan Water and Sewerage Board, Albert-street, BRISBANE, Queensland, want tenders by noon Jan. 30 next for supply and erection, of one, two or three complete units, each consisting of power generating plant and pump or pumps to lift not less than 6,000,000 gallons per day. Particulars from the Secretary, and forms from the Agent-General for Queensland.

The Municipal Council of BUDAPEST, Hungary, require tenders for the manufacture and supply of plant for a steam-driven electrical generating station, including two groups of three-phase turbo-generators (5,000 kw. each), 10,000 volts 50 cycles, boiler equipment for mechanical output of 5,000 kw. with reserve, pipeline, central switching and accessory equipments, travelling crane for engine room and coal-conveying plant. Specifications, &c., can be obtained at the Presidial Section of the Council, 9: IV., Városház-utca 16, II. 1, Budapest. Tenders by 11 a.m. Sept. 30.

The BOMBAY, BARODA & CENTRAL INDIA RAILWAY Co. want tenders by noon Aug. 22 for supply of steam engines and d.c. dynamos, air compressors and centrifugal pumps. Forms of tender, &c., from the Secretary, 110, Bishopsgate, London, E.C.

Tenders will be received at the Town Hall, SYZRAN, Russia, on Oct. 14, for the construction of an electric tramway and the supply of electrical energy for lighting.

The Public Works Department, Madrid, will receive tenders on Sept. 20 for the concession for the construction of the RENTERIA electric tramway.

Digitized by Google

The time for the receipt of tenders by the Ministry of Public Works, Constantinople, for an electric power and tramway concession for JERUSALEM, is extended to Sept. 13. Specifications (in French) can be seen at 73, Basinghall-street, London, E.C.

The Municipal Commissioners of PENANG invite tenders for the supply and delivery, f.o.b. British port, of one 500 kw. steam dynamo engine or turbine with ejector condensing plant and switchgear. Specifications, general conditions and form of tender may be obtained from the consulting engineers, Messrs. Preece, Cardew & Snell, 8, Queen Anne's-gate, Westminster, S.W., to whom tenders (in duplicate) are to be sent by noon of Tuesday, Sept. 5.

TENDERS RECEIVED AND ACCEPTED.

The Balmain Electric Light & Power Supply Co. (Balmain, Australia) have placed an order with Willans & Robinson for a 500 kw. Willans impulse disc and drum mixed-pressure steam turbine, coupled to a General Electric alternator and exciter. The turbine will exhaust into a vacuum-augmentor surface condensing plant, which Willans & Robinson will also supply.

Sydney (N.S.W.) Municipal Council have accepted the following tenders:—

Noyes Bros., for the supply of electric motors; with the local agents of Ferranti Limited and the Allgemeine Elektricitäts Gesellschaft, for electricity meters; Union Electric Co., five Excello flame arc lamps and arc lamp carbons; British Insulated & Helsby Cables, for cables (11,000 volt), £2,420; Gordon, Marr & Sons, bases for steel poles (351), c.i. arc lamp bases, £170; G. H. Olding, tower and pole erecting waggons (two of each), £329; Australian General Electric Co., transformers and switchgear, £417; British General Electric Co., "Osram" lamps (with a guaranteed life of 2,000 hours), £533. 6s. 8d.

Willans & Robinson have received an order from the War Office for three Willans-Diesel direct-current generating sets to the specification of Messrs. Kennedy & Jenkin for the Bordon Camp electricity supply.

Bangor Council have placed an order with the Diesel Engine Co. for a 100 kw. Diesel oil-driven generating set.

Walsall Council have accepted the tender of J. Storey & Sons for supplying two sets of jet condensing plant at £1,163.

The contract for the pumping machinery for the Montreal filtration scheme has been let to the British Electric Plant Co. at $40,000.

Government Contracts.—The British Government Departments have placed the following contracts during July:—

India Office (Stores Department):—British Insulated & Helsby Cables and W. T. Henley's Telegraph Works Co., cable; British Westinghouse Electric & Mfg. Co., dynamos.

Crown Agents for the Colonies.—Mavor & Coulson, electric light plant and fittings; Bullers Ltd., insulators; British L. M. Ericsson Mfg. Co., telephone material; T. Bolton & Sons, copper wire.

H.M. Office of Works.—Howell J. Williams (Ltd.), Western telephone exchange erection; Browett, Lindley & Co., generating set for South Kensington.

G.P.O. (Stores Department).—British Insulated & Helsby Cables, telephone cases, signalling apparatus, jacks, &c.; Western Electric Co., loading coils and protectors; Western Electric Co., generators; Gent & Co., house telephone apparatus; British L. M. Ericsson Mfg. Co., and British Insulated & Helsby Cables, telephones; Peel-Conner Telephone Works, inset transmitters; Millars Karri & Jarrah Co. (1902), wood arms; W. T. Henley's Telegraph Works Co., indiarubber and cotton core cable; Siemens Bros. & Co., submarine cable; J. Wilesmith & Co., casing and covers for electric wiring; G. Skey & Co., earthenware ducts; Bullers Ltd., insulator spindles; F. Smith & Co., copper wire; C. MacIntosh & Co., flameproof wire; R. Johnson & Nephew, galvanised iron wire.

G.P.O. (Engineering Department).—Spencer & Co., band conveyor at Bristol P.O.; Western Electric Co., telephone exchange extensions at Hendley, Croydon and Central Exchange (London); Peel-Conner Telephone Works, telephone exchange equipment at Blackpool and Worcester; British Insulated & Helsby Cables, telephone exchange equipment, Worthing.

Commissioners of Woods.—Wellman Bros & Co., electrical installation Cumberland Lodge, Windsor Great Park.

Commonwealth Tenders.—The following contracts have been placed by Australian Government Departments:—

South Australia Postmaster-General's Dept. India Rubber, Gutta Percha & Telegraph Works Co., 3,000 primary battery zincs, 8¼d. each. Western Australia Railway Department. Doulton & Co., 5,000 Cordeaux insulators, £170. 14s. 6d.; Public Works Department. General Electric Co., triple expansion pumping engine, £1,580.

BUSINESS NOTICES.

The partnership between Messrs. Wm. Charles Cloete Hawtayne and Geo. Alex. Zeden, carrying on business as consulting engineers, Queen-street-place, London, E.C., under the style of Hawtayne & Zeden has been dissolved as from June 30, 1911. Debts by Mr. C. C. Hawtayne who will continue in his own name.

The London & Rugby Engineering Co. (Ltd.) 10, Bush-lane, Cannon-street, E.C., have acquired the business of Messrs. J. L. Cateaux & Co., including all assets and liabilities, as from July 1, 1911. Accounts owing by Messrs. Cateaux & Co. will be settled by them as they become due. The company will be managed by the principals of the old firm.

Mr. F. L. Rawson, consulting engineer, has removed his offices to 3, London Wall-buildings, E.C.

Patent Development.—The proprietors of patent No. 4,927/07 for "Improvements in or relating to electric furnaces" desire to make arrangements for exploiting same in this country. Communications to Messrs. Haseltine, Lake & Co., patent agents, 7 and 8, Southampton-buildings, Chancery-lane, London, W.C.

The owners of patent No. 23,501/99, relating to "Improvements in Vacuum Tube Lighting," and patent No. 12,582/02, relating to "An Improved System of Electric Lighting," also desire to negotiate with electrical engineers with the view of granting licences. Applications of Messrs. Lloyd Wise & Co., patent agents, 46, Lincoln's Inn Fields, W.C.

BANKRUPTCIES, LIQUIDATIONS, &c.

Frederick Vickers (trading as Frederick Vickers & Co.), electrical engineer, 286, Oxford-road, Manchester, has been adjudicated bankrupt. First meeting of creditors Aug. 23 at O.R.'s, Byrom-street, Manchester, and public examination on Aug. 25 at the Court House, Quay-street, Manchester.

A dividend of 3s. 4d. in the £ is payable at 27, Brazennose-street, Manchester, to creditors of Chas. Hellyer Pearson, electrical engineer, &c., 51A, Mosley-street and Stockton-street, Manchester, and 4, Manchester-road, Hyde.

A meeting will be held on Sept. 15 at 1, Cecil-chambers West, London, W.C., to receive an account of the winding up of the Lepel Wireless Synd. (Ltd.)

A meeting will be held on Sept. 12 at 52, Moorgate-street, London, E. C., to receive an account of the winding up of the Rosario Electric Co. (Ltd.)

A meeting will be held on Sept. 12 at 23, Grafton-street, London, W., to receive an account of the winding up of the Alliance Electrical Co. (Ltd.). This company was wound up with a view to the sale of its undertaking to the Alliance Electrical Stores (Ltd.)

COMPANIES' MEETINGS AND REPORTS.

DUBLIN & LUCAN ELECTRIC RAILWAY CO.—Gross receipts for the half-year amounted to £3,455. 11s. 3d., a decrease of £6 on the corresponding period of 1910, whilst expenditure increased by £276. 13s. 8d., mainly in coal and repairs to plant. After providing debenture interest the available balance is £919 17s. 3d., and the directors recommend payment of the usual half-yearly preference dividend, £444. 17s. 3d. being carried forward.

GREAT NORTHERN RLY. CO.—At the meeting last week the chairman (Lord Allerton) said the company had spent £143,000 on the Great Northern, Piccadilly and Brompton Railway in making the connection at Finsbury Park. They received from that company in the half-year £4,922 and from the Great Northern and City Co. £8,675.

LANCASHIRE & YORKSHIRE RLY. CO.—At the meeting last week the chairman (Sir Geo. Armytage) stated they were paying 4¼ per cent., the best dividend paid for 11 years. They had continued the electrification of their line to Town Green. Half of the total increase in the number of passengers was on their electrified lines—their last extension to Town Green was already showing gratifying results.

LIVERPOOL OVERHEAD RAILWAY CO.—The chairman (Sir Wm. Forwood) stated at the meeting on Tuesday that it was gratifying to place before the meeting a statement of a distinctly encouraging character. The improvement was due to the increased trade of the port, good weather and economy in working. During the past few years they had strengthened the main structure from end to end, and the cost had been paid out of revenue. During the past half-year they had carried on their railway and tramlines 5,393,597 passengers, against 5,090,080 during the same half last year, but the value per passenger had fallen from 1·72d. to 1·69d., owing to an increased proportion of workmen's traffic. Their revenue showed the satisfactory increase of £1,968, and they had earned that increased revenue at a cost of only £382. Their expenditure worked out at 66·16 per cent. of revenue, against 69·84 per cent. Their cost per train-mile had been 12·02d., against 14·2d. on the City and South London, and 21·51d. on the Mersey Railway. Their railway carried 4,226,410 passengers, the City and South London carried 12,413,000, and the Mersey Railway 6,027,000. All they wanted was increased traffic. They had £10,841. 6s. 1d. available for dividend, and recommended payment of the preference dividend and 1 per cent. on the ordinary shares, which would leave £4,665. 9s. 1d. to be carried forward. The bill for consolidating their borrowing powers, and to enable the Mersey Dock Board to guarantee the interest on the debenture stock, now awaits Royal Assent.

Digitized by Google

LONDON ELECTRIC RAILWAY CO.—Lord Geo. Hamilton stated at the meeting last week that the capital expenditure during the half-year amounted to £47,222. The most important item of that expenditure was the cost incurred in the establishment of the "escalator" at Earl's-court, which would very shortly be completed. Extensive alterations were also being made at the Highgate Station on the Highgate-Hampstead line. The London Electric Railway Act of 1900, which received the Royal Assent on June 2, authorised the extension of the Bakerloo line to Paddington Station and the Hampstead-Highgate line from Charing-cross to the Embankment. Tenders for those two extensions had been received by the company; the contract would be let within a few days and the work would be proceeded with continuously. The gross receipts for the six months amounted to £392,817, an increase of £27,193 over the corresponding period for the preceding year. The working expenses were £174,919, an increase of £7,699. The ratio of working expenses to gross earnings had diminished to 45·53 per cent. They proposed to pay 4 per cent. on the preferred stock and 1 per cent. on the ordinary stock, and to carry forward £14,506, as against £12,401 for the corresponding period last year. Not a single serious accident occurred among the millions of passengers carried during Coronation week, a result which reflected high credit both upon those who made as well as those who gave effect to the arrangements. The negotiations with the Underground Electric Railways Co. of London for the sale of the power-house to the Joint Committee of the London Electric and District Railways had been successfully concluded, and he could safely say that the bargain was a fair one for all the parties concerned.

METROPOLITAN DISTRICT RAILWAY CO.—Lord Geo. Hamilton, who presided at the meeting last week, stated that the capital expenditure for the past half-year was £88,663, of which £12,472 was spent upon reconstruction and improvement of stations, and £39,517 on the construction of new cars. For the current half-year they estimated they should spend £90,000 on capital account, including £51,000 for new rolling stock, leaving £78,000 to be incurred in subsequent years. There was an increase of £27,124 in gross receipts, and in passengers of 4,359,000 over the number carried in the corresponding period of last half-year. The Coronation and its festivities contributed to the increase, also the opening of the Earl's Court Exhibition grounds. But apart from the Coronation their traffic showed a general and satisfactory increase. Their working expenses showed an increase of £9,410, due to improved and increased train service, extensions, improvements in rolling stock, &c. The operating expenses per car-mile showed a reduction of 0·006d., and per car-hour of 0·259d. The percentage of operating expenses to gross receipts was 46·69. The arrangements made to meet the exceptional strain of the Coronation week worked most successfully, and reflected high credit alike upon the directing staff and employes under them. There was no hitch throughout the period, and not a single accident amongst the millions of passengers carried. They had a balance available for dividends of £82,091, an increase of £20,715 including the balance of £2,020 from last half-year. They proposed to pay the full dividend on the 4½ per cent. first preference stock, leaving a carry forward of £14,277, against £8,528. Although sufficient had been earned to pay a small dividend on the 5 per cent. second preference stock the directors did not recommend any payment. The half-year had been an exceptional one, and the directors deemed it advisable to take advantage of the opportunity to strengthen the reserve funds. It was 27 years ago that the last full dividend on the first preference stock was paid; that dividend gradually diminished, and from June, 1900, to Dec., 1909, it ceased altogether, but now they had the full 4½ per cent. The development of the traffic had been satisfactory and continuous in recent years. Rapid progress continued to be made with the widening of the railway between Ravenscourt Park and Acton-lane junction. They expected to work over the new lines by November. That would afford their company an opportunity of working a closer and more regular service of trains to Ealing and other points on the western lines. Another improvement which will benefit their company was the extension of the London Electric Railway from Charing Cross to the Embankment station. The lessee companies of the East London Railway had agreed to a scheme for electrifying that line. Negotiations were in progress with the East London Co., and it was hoped that matters would be finally adjusted, so that the work could be put in hand at a very early date. One of the lessee companies was to provide the necessary capital required for the electrification of the line. Terms for the supply of electrical energy, which was to come from the Lot's-road power house, had been agreed with the District Company. The negotiations with the Underground Electric Railways Co. of London for the sale of the Lot's-road power house to the Joint Committee of London Electric and the District Companies had been concluded, and the bargain was a fair one for all parties concerned. The power house would be transferred to a Joint Committee of six, three members of the Board of that company and three members of the Board of the London Electric Railway Co.

NEW GENERAL TRACTION CO. (LTD.)—Baron E. B. d'Erlanger stated at the meeting on Friday that the dividends and interest received from their sub-companies amounted to £22,656, against £19,482 in the previous year. The Coventry Co. paid 5⅞ per cent. dividend, against 3½. The dividend from Norwich showed a decrease of £900, but they received from their Philadelphia undertaking 4 per cent. instead of 3 per cent. The general expenses showed an increase of £355. The resulting balance was £3,674. 18s. 6d., compared with £500. 19s. 4d. Coventry Corporation had given notice of intention to acquire the local tramways. The Corporation had been invited to name the amount which they would be prepared to pay for the undertaking, but they were unwilling to do so, and as the company were unwilling sellers it was not prepared to state a price at which it would sell. Consequently the matter would be the subject of arbitration, the date of which was not yet fixed. The Douglas Southern Tramway pursued the even tenor of its way, and paid a dividend of 5 per cent. on its preference shares for the year ended October, 1910, the same as in the preceding year.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES, &c.

NEW COMPANY.

BRAUNTON ELECTRIC LIGHT & POWER CO. (LTD.) (117,202.)—Reg. Aug. 10, capital £5,000 in £1 shares, to carry on the business indicated by the title, and to adopt agreements between S. I. Knill and the Parish Council of Braunton and between S. I. Knill and Crompton & Co. First directors T. Yeo, H. S. G. Clarke and H. K. Symonds.

STATUTORY RETURNS.

AFRICAN DIRECT TELEGRAPH CO. (LTD.)—In the return to June 14, capital is £300,000 in £10 shares. 23,600 shares taken up. £236,000 paid. Mortgages and charges £8,600.

LANDAULET CO. (LTD.)—Return to June 7 gives capital £50,000 in £10 shares. 3,928 shares taken up. £39,280 paid. Mortgages and charges £6,000.

MORTGAGES AND CHARGES.

ELECTROMOBILE CO. (LTD.)—Particulars of £11,807 debentures, created Aug. 3, have been filed, amount of present issue being £6,566. 18s. 11d. Property charged: Company's undertaking and property, present and future, including uncalled capital. No trustees.

Issue on Aug. 3 of £10,000 debenture stock, part of a series secured by trust deed dated Dec. 9, 1903, between the North of England Trustee, Debenture & Assets Corpn. and this company also received. The stock was limited in the first instance to £40,000, but has been increased to £50,000.

LODGE-MUIRHEAD WIRELESS & GENERAL TELEGRAPHY SYND. (LTD.)—Particulars of £10,000 debentures, created July 21, have been filed, the whole amount being now issued. Property charged: Company's undertaking and property, present and future, including uncalled capital. No trustees.

CITY NOTES.

MEMORANDA (Aug. 10).—Bank rate 3 per cent. (March 9, 1911.) Price of silver, 24⅞d. per oz. Consols 78⅝ for money and for account. Consols Pay Day, Sept. 1; Stock and Shares Continuation Days, Aug. 29 and Sept. 12; Ticket Days, Aug. 30 and Sept. 15; Pay Days, Aug. 31 and Sept. 14; Mining Shares Carry Over Days, Aug. 28 and Sept. 11.

PRICES OF METALS (London).—*Copper*, cash, 56½; three months, 57. *Lead*, English, 14¼—14½; Foreign, cash, 14; three months, £14. *Spelter*, 27—27½. *Tin*, English, 191—193; Foreign, cash, 190; three months, 187. *Iron*, Cleveland, cash, 47/6, three months, 48/3.

CALCUTTA ELECTRIC SUPPLY CORPN. (LTD.)—The number of units delivered to consumers during the five weeks ended June 30 were 1,050,023, compared with 995,992 units in the corresponding five weeks of 1910.

W. T. HENLEY'S TELEGRAPH WORKS CO. (LTD.)—The directors have declared an interim dividend on the preference shares at the rate of 4½ per cent. per annum (less tax), and on the ordinary shares at the rate of 10 per cent. per annum (tax free) for the half-year ended June 30, both payable Sept. 1.

NEWCASTLE & DISTRICT ELECTRIC LIGHTING CO. (LTD.)—The directors have declared an interim dividend at the rate of 3 per cent. per annum for the half-year ended June 30, absorbing £4,456, and carrying forward £6,885, against £2,917 for the corresponding half-year of 1910.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed Aug. 30 a special settling day in £200,000 5 per cent. mortgage debenture stock of the *British Insulated & Helsby Cables (Ltd.)* and have ordered the further issue of £205,480 4½ per cent. perpetual consolidated mortgage debenture stock, $500,000 additional common stock and $250,000 additional 5 per cent. consolidated first mortgage bonds of $1,000 each of the *Shawinigan Water and Power Co.* to be quoted in the Official List. The Committee have also been asked to allow £1,000,000 general mortgage 4½ per cent. 30-year gold bonds of $1,000 each of the *Consolidated Gas, Electric Light and Power Co. of Baltimore* and $7,580,000 1st mortgage sinking fund 5 per cent. gold bonds of $1,000 each of the *Pennsylvania Water and Power Co.* to be quoted.

TYNESIDE TRAMWAYS & TRAMROADS CO.—The directors recommend a dividend of 1¼ per cent. per annum (1s. 6d. per share), less tax, on the ordinary shares for the half-year, placing £1,000 to reserve for renewals, depreciation, &c., writing £530 off preliminary expenses and carrying forward £620.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON (LTD.)—Interim on the income bonds for the half-year ended June 30 at the rate of 1 per cent. per annum (tax free) will be paid on Sept. 1.

WASTE HEAT & GAS ELECTRICAL GENERATING STATIONS (LTD.)—The directors have declared an interim dividend at the rate of 5 per cent. in respect of the half-year ended July 31 (less tax), payable 31st inst.

NOTES.

Labour Unrest.

"COMPLETE paralysis" did not overtake the railways, and in only a few cases was there even partial paralysis. Some of the underground and tube railways of London were affected in varying degrees, but most maintained a reasonably good service. At no place has there been serious trouble with electrical workers, although at one period the situation at Liverpool was alarming. There, we are officially informed, the men employed by the Corporation Electric Supply Department had no grievance whatever with respect to their employment, but were withdrawn by the orders of the local strike committee. The only effect was to curtail the tramway, power and lighting supplies, and, incidentally, to provide certain young professional and independent men with a novel experience. These young men immediately came forward and volunteered to assist in the running of the generating stations. As a result, a modified tramway service was kept going during the day and the city was lighted by night.

A REQUEST was sent to the Government that navy stokers and electricians should be detailed for the duty of keeping the supply going in the absence of the employés, but it is doubtful whether matters had reached the stage when State assistance becomes necessary. It is probable that great danger to the public would result from a cessation of supply of electricity for lighting purposes, and the duties of police and military might be rendered impossible of execution. In such an event it would undoubtedly become necessary for the Government to take steps to secure that supply should be maintained whether the supply authority were a company or a municipality. There would be no question of taking sides with employer or employed; the safety of the public would necessitate State assistance as distinct from mere protection. Fortunately, the necessity has not yet arisen; but, as prevention is always better than cure, perhaps the time is not inopportune for the consideration of legislation aimed at breaches of contract on the part of those workmen engaged in the supply of electricity, gas and water.

Drawn Wire Lamps.

ON another page of this issue we refer to the factory which the British Thomson-Houston Co. have equipped at Rugby for the production of metal lamps. Until quite recently this factory was devoted to the manufacture of pressed filament lamps, but developments have recently taken place resulting in the replacement of the old equipment by plant and apparatus for the manufacture of drawn wire tungsten lamps in large quantities. The drawing down of tungsten to wire of very small section must be regarded as a notable step in the development of the metal lamp, and although the Company have not yet divulged particulars of the means by which the improvement has been brought about, there can be no mistake about the ease with which the wire, when drawn, is handled and attached to the supporting frames inside the lamps. This development has resulted in the production of a lamp which, at the time of its purchase, may be handled with comparative impunity. This is a point of great importance, for the most serious defects of metal lamps have been

Digitized by Google

experienced before use. Further, it is probable that the new process will result in lessening the cost of manufacture; for the placing of the drawn filament in position on the supports is performed in two operations, as compared with at least half-a-dozen in the case of the pressed filament. The new "Mazda" lamp enters the field at an important moment; at the Olympia Exhibition next month great efforts will be made to bring electricity consuming devices of every description before the public, and any process of manufacture which promises a reduction in the price of metal lamps is therefore to be welcomed.

Compulsory Electrification.

For some time past the authorities of Boston (U.S.A.) have been coquetting with the traffic problem in that city, with the result, as will be seen by reference to another column, that a bill has been introduced into the Massachusetts State Legislature making compulsory the electrification of all railway lines within the 10-mile radius. This is a drastic measure, and must, we feel sure, like most other amateur legislation, have been proposed as a remedy for existing troubles without proper consideration of the problems involved. It is not to be wondered at, therefore, that the New York, New Haven and Hartford Railway Co., the undertaking primarily concerned, have entered a protest against this high-handed proceeding. While we are naturally favourable to the employment of electric traction where its use is likely to be beneficial either at once or in the future, we have never lost sight of the fact that all changes of this kind must be gradual and voluntary. As the railway authorities point out, the change will cost £8,000,000, a sum which cannot be raised without neglecting the requirements of other districts, while so large an increase in the capital account is not unlikely to have a bad effect on railway securities generally and to cause a general increase in passenger and goods rates, besides decreasing the dividends.

It is as well (for schemes of this kind have also been proposed in this country) that we should recognise that all changes from steam to electrical working must be gradual. The fresh capital expenditure necessary makes careful consideration of each scheme essential, and although we are not well enough acquainted with the traffic conditions at Boston to say how far its suburban lines would respond to electrification by an increase in traffic, it is evident that the railway company have grave doubts on the point. Surely, too, if the municipal authorities are of opinion that the electrification of these lines is essential for the public welfare, it would be better for them to provide the funds by loan than to expect the directors of a railway company, having their shareholders to consider, to spend fresh capital in gratification of their whims. The whole affair, taking place as it does in a free country, is not without a taste of mordant humour.

Energy Losses in Telephony.—In an article published in the "Elektrotechnische Zeitschift," Mr. F. Breisig gives an account of some experiments undertaken by him with a view to determining the different losses in telephone apparatus. For the tests a permanent alternating current with a frequency of 800 was used. The telephone was used in the same way as it is employed in practice, namely, the receiver being taken off during speaking. The connections of the central battery system were used. It was found that, during receiving, out of the total electrical energy received 70·5 per cent. was lost in the microphone, 1·6 per cent. in the bell, 18·4 was supplied to the telephone, the loss in the primary winding being 3·4, in the secondary winding 3·4 and the losses in the other coils 2·7. The chief source of loss was in the microphone, and, since it is entirely unnecessary while receiving, it might be short-circuited at that time, but this would cause trouble on account of its high resistance. To avoid this trouble and to reduce the alternating-current impedance, a condenser of 2 mfd. was connected in parallel with the microphone when receiving. When speaking, it was disconnected by means of a simple switch. With this arrangement the above figures of losses were greatly changed. The loss in the microphone was now only 12·2 per cent., the loss in the bell 1·1, while 57·2 per cent. of the energy was delivered to the telephone and 29·6 was lost in the coil. The influence of the microphone might also be reduced successfully by using a higher number of turns for the primary coil.

Electric Tramway Regulations in New Zealand.—According to "The Times Engineering Supplement" the Government of New Zealand has made its first move towards exercising the unlimited powers of regulation of tramways that it recently obtained by the passing of an amending Tramway Act. This Act was before Parliament for three years, and in each year vigorous opposition by the municipal authorities of the country was made to it on the grounds that the present services were efficiently and successfully operated by the City Councils concerned, and that Government interference to the extent made possible by the Bill meant State management without State financial responsibility. The new law makes it possible for the Minister of Public Works to impose regulations, even to the extent of overriding authorising orders, without reference to any one; but the first batch proposed have just been referred to the municipal tramway authorities for their suggestions. Included are stringent provisions as to overcrowding, carrying passengers beyond the seating capacity of cars, and many traffic details, while car construction must be brought into conformity with the provisions now laid down. It is even decreed that portable steps must be carried on some classes of cars, and set down on the roadway when demanded by passengers. Very small scope is left to authorities in their future choice of plant, almost every item being placed on a compulsory list. One regulation stipulates that the gap on car lightning arresters shall be $\frac{1}{32}$ in., and minute directions for valves, details of sanding gear, &c., are laid down. The publication of these regulations has roused a storm of protest, ridicule, and even defiance. One Mayor describes the regulations as "a gigantic steal" intended to force the cities to hand over the tramways to the Government. The engineer of the Wellington tramways has advised his Council that it will cost that system £75,000 to comply with the regulations, that the additional annual cost will amount to £40,000 and that fares will have to be increased about 50 per cent. to meet the outlay.

Compulsory Electrification of Railways.—According to "Engineering News," the Bill which will make compulsory the electrification of the Boston railway termini is being strongly opposed by the New York, New Haven & Hartford Railroad Co. In a circular letter the Railway Company says:—

Except where use of tunnels is rendered less dangerous by use of electricity, there has been no compulsory electrification of railroads. All the electrification of the New Haven has been without compulsory legislation. The New Haven has repeatedly stated its desire and willingness to electrify. This year it proposes to electrify from Readville on the Boston & Providence and to Beverly on the Boston & Maine. Electrification of

Digitized by Google

short distances, say 10 miles, has never been found at all economical, and a compulsory electrification within a 10-mile limit will be unusually uneconomical. Money required for electrification must be raised by the issue of new securities, and unless the money for electrification is wisely and economically expended, there will be placed upon railroad transportation a very serious charge which can only be met by increased freight and passenger rates. The best business interests of New England require these rates to be kept as low as possible, consistent with safety. It is proposed to discriminate against every other city and town of this Commonwealth in favour of the district within 10 miles of the city of Boston. It is estimated that the cost of electrification in this district will amount to approximately $40,000,000 (£8,000,000). If the railroads are called upon to make this expenditure in the city of Boston and vicinity; and if the proceeds of securities which the railroad corporations can find the public willing to purchase must be expended in this electrification, then other railroad improvements must necessarily wait. Electrification in other parts of the Commonwealth must wait because there is a limit to the amount of money which the public will invest in railroad securities. If it is understood by the investing public that the Massachusetts legislature proposes deliberately to take the management of its railroads out of the hands of the boards of directors, and to pass that management over to the State Railroad Commission, we venture to assert that investors in Massachusetts railroad securities will be much less willing to add to their investments. We especially recall to the attention of the Senate the report of the majority of the "Big Four Commission" and the statement of Prof. Geo. F. Swain before the joint committees of this legislature. We respectfully request that the judgment of 11 out of 16 members of the "Big Four Commission" be followed by the legislature; and that the management of the railroads be allowed to remain with the railroad directors, subject to the supervision, regulation and recommendation of the Board of Railroad Commisioners. We do not in this brief statement consider whether the Bill is or is not constitutional.

Railway Commission.—In connection with the serious labour trouble in the railway world, the Government have appointed a Royal Commission of five members to consider and report upon the working of the present Conciliation Boards. The members of the Commission are: Sir David Harrell, K.C.B., K.C.V.O. (chairman); Sir Thomas Ratcliffe Ellis; Mr. Arthur Henderson, M.P.; Mr. C. Gabriel Beale (Birmingham), solicitor to the Midland Railway Co., and Mr. John Burnett, formerly Labour Secretary to the Board of Trade. Mr. J. J. Willis, of the Board of Trade, is secretary to the Commission.

French Submarine Cables.—The French c.s. "François Arago," of the Société Industrielle des Téléphones, left Calais on the evening of Thursday, August 17th, to lay cables on the West African coast between Libreville-Cap Lopez and Loango Pointe Noire in the Congo region, to the order of the Ministry of the Colonies for French Equatorial Africa. The cable has been manufactured by the Société Industrielle, the core having been made at the works at Bezons. Its total length is some 300 nauts. The "François Arago" is due at Libreville early in September, and it is expected that the cables will be laid and open for traffic in October. The French Government engineer on the expedition is M. Marcel Charruau. The engineer-in-chief is M. Maurice Roussel, who has been associated with the Société for many years.

Electrically Driven Luggage Trucks.—According to the "Railway and Engineering Review" a truck driven by accumulators is being used by the Erie Railroad at Jersey City. The power for operating the truck is derived from a single storage battery consisting of two sets of 12 cells each, the capacity of which is 120 ampere-hours at 60 volts. Power is taken from the batteries through a fuse, circuit breaker and a drum-type controller, the latter being mounted in ball bearings between the two frame members. It is connected to a set of resistances, and is operated by a vertical lever moving in a vertical plane within convenient reach of the operator's left hand, through an arc of about 120 deg., giving five forward speeds and five reverse. No power can be transmitted to the controller, however, unless the foot pedal, which simultaneously releases the band brake on the jack shaft and throws in the circuit breaker, has been pushed down. The controller regulates the amount of current sent into the motor through resistances which are placed between the controller and the jack shaft. The 2½ H.P. motor is also mounted between the frame members, just behind the leading axle. The form of drive employed allows of speed changes in five steps of from 2 to 12 miles per hour, in either direction, under a load of about 2,500 lbs. on a truck 10 ft. 2 in. in length, and 42 in. wide.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

We describe a new underground electric railway in Paris—the North-South line.

At a recent meeting of the American Institute of Electrical Engineers, Mr. Bancroft Gherardi read a Paper on "The Commercial Loading of Telephone Circuits in the Bell System."

We give an abstract of a Paper read by Messrs. J. T. Morris and T. H. Langford before the Physical Society on "The Method of Constant Rate of Change of Flux as a Standard for determining Magnetisation Curves of Iron."

The British Thomson-Houston Co. are now supplying lamps in which drawn filaments are used. A description is given of the production of the new lamps at Rugby.

We analyse the accounts of the Glasgow Corporation tramway department for the year ended May 31, 1911. After allocating 2·24d. per car-mile for depreciation, £68,678 is handed over for the relief of the rates.

A description is given of the automatic telephone installation of the Illinois Tunnel Co. at Chicago.

The report of Lieut.-Col. P. G. von Donop, R.E., on the tramway accident on the Stalybridge tramways has been issued.

Some particulars are given of a scheme for the formation of a trust syndicate to control the electric lighting and traction concessions at Constantinople.

The award of the Board of Trade arbitrator, Mr. Askwith, K.C., in connection with the recent Leeds tramway dispute is given in another column.

Parliamentary.—The Royal Assent was read to a number of new Acts on Friday.

In the House of Commons on Monday Mr. Churchill was questioned as to the cause for sending soldiers to occupy the Poplar electricity works during the recent strike troubles in the East End.

On Friday the Postmaster-General stated, in reply to a question, the principles upon which the various Government Departments acted in carrying out the fair wages clause.

Companies' Reports.—The reports of the following companies are abstracted: British Continental Electricity Co., Brown, Boveri & Co., Kalgoorlie Electric Tramways and Perth (W.A.) Electric Tramways. A dividend of 7 per cent. has been declared by Brown, Boveri & Co., against 8 per cent. in 1909-10. The report deals with the condition of the electrical industry on the Continent and the problems involved in railway electrification.

OBITUARY.

THE REV. F. J. JERVIS-SMITH, F.R.S.—We regret to record the death of the Rev. Frederick John Jervis-Smith, F.R.S., which occurred at Battramsley House, Lymington, on Wednesday last. The deceased was in his 64th year. He was educated at Pembroke College Oxford, and for two years was vicar of St. John's, Taunton. Subsequently he was appointed University Lecturer in Mechanics at Oxford and Millard Lecturer in Experimental Mechanics and Engineering at Trinity College. He was a member of the Committee on Explosions at the Home Office in 1895-96, and was the inventor of several forms of dynamometers, integrators and chronographs.

S. H. BURBURY.—We also regret to have to record the death, at 80 years of age, of Mr. S. H. Burbury, F.R.S., who is best known for his work in mathematical physics. He was the joint author (with Mr. H. W. Watson) of works on "Electrostatics" and "Electrodynamics."

PERSONAL NOTE.

The German Emperor has nominated Sir W. Ramsay, K.C.B., F.R.S., professor of chemistry in University College, London, and president-elect of the British Association, to the Order Pour le Mérite, for his services to science.

APPOINTMENTS VACANT AND FILLED.

An assistant lecturer and demonstrator in physics is required at the East London College). Commencing salary £150. Particulars from Prof. C. H. Lees, or the Registrar, at the College, Mile End-road, E.

Digitized by Google

A lecturer in the engineering department (commencing at £150 to £180 and rising to £250) and a chief assistant in the chemistry department (commencing £150 to £170 and rising to £250) are required at the Borough Polytecchnic Institute, Borough-road, London, S.E. Conditions, &c., from the principal, Mr. C. T. Millis.

A lecturer and instructor in telephony (for one evening) and a teacher of manipulative telegraphy (for two evenings per week) are required at the Wimbledon Technical Institute. Applications to the Principal, Gladstone-road, Wimbledon. See an advertisement.

An electrical engineer is wanted familiar with electrical and mechanical design of d.c. motors. Applicants must be technical graduates and read and speak English. See an advertisement.

One or two draughtsmen are wanted by a large electrical firm. Must be used to switchgear design, &c. See an advertisement.

Marconi's Wireless Telegraph Co., Watergate House, Adelphi, London, W.C., have vacancies for two electrical engineers in Spain. See advertisement.

An assistant draughtsman is required by Messrs. Harland & Wolff (Ltd.), Belfast, to prepare wiring plans and diagrams and get out quantities, &c., of installations for ships. See an advertisement,

---

Mr. R. F. Pack has been appointed general manager of the Toronto Electric Light Co.

Mr. Oscar Beabey, late of the San Paulo Railway, has been appointed telegraph engineer to the Buenos Ayres Pacific Railway Co.

Mr. H. Vickers, Wolverhampton, has been appointed assistant tramways engineer at Bournemouth.

EDUCATIONAL NOTICES.

University of Sheffield.—The faculty of applied science comprises the departments of engineering, metallurgy, coal mining and architecture. The courses in engineering or in metallurgy extend over three years and prepare respectively for the degree of B.Eng. or B.Met. of the university. The lecture courses commence on Oct. 4, and the technical laboratory courses on Sept. 18. Prospectuses and other particulars from the registrar, Mr. W. M. Gibbons.

University of Durham.—Armstrong College, Newcastle-upon-Tyne.—The 1911-12 session commences Sept. 25. There are departments of mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars may be obtained from the secretary, Mr. F. H. Pruen, M.A.

Imperial College of Science and Technology.—During the 1911-12 session an advanced course of instruction on the systematic design and manufacture of dynamo-electric machinery will be given at the City and Guilds (Engineering) College, Exhibition-road, London, S.W., under the general supervision of Prof. T. Mather, F.R.S.

The course is intended for post graduates and other fully qualified students, the number of whom will be limited. The lectures (about 45 in number) will be delivered during the first half of the session by Mr. W. E. Robson, M.I.E.E., and the practical work will commence in October and continue throughout the session. Ratings, frame sizes, windings, &c., for complete lines of machines will be considered in detail, as well as works organisation for systematic manufacture. In addition to lectures, practice in designing, estimating and drawing office work will be given, and advanced laboratory work relating to the limiting conditions existing in modern machines. Applications for admission to the Dean of the College, Exhibition-road, London, S.W.

City and Guilds Technical College.—This college provides a scientific training for students preparing to become electrical and mechanical engineers or chemists, and for engineering pupils who desire to supplement their practical training by a two years' course of instruction in the principles of engineering science. There are also arrangements for three-year courses in engineering. Particulars at the college, Leonard-street, City-road, London, E.C., or from the City and Guilds of London Institute, Gresham College, Basinghall-street, London, E.C.

Glasgow and West of Scotland Technical College.—The diploma of the college is granted in the departments of civil, electrical and mechanical engineering, mining, naval architecture, chemistry, metallurgy, mathematics and physics, building and textile manufactures. The courses of study usually extend over three sessions, and holders of the diploma are eligible for the degree of B.Sc. in engineering of the University of Glasgow, after attendance for at least one session at prescribed university classes. The laboratories are well equipped, and facilities for research are afforded in the departments of physics, electrical engineering, chemistry, metallurgy, mechanics, &c. The preliminary examination begins on Sept. 18, and names of candidates must be sent in by Sept. 1. The day classes begin Sept. 26 and the evening classes Sept. 21. Calendar (by post 1s. 4d.) and prospectuses (gratis) will be sent on application to the Director.

City of Bradford Technical College.—At this college there are full day courses qualifying for the college diploma in civil, mechanical and electrical engineering. The next session commences Sept. 18. The new power house, especially arranged for experimental and educational work, will be opened during the session, and the equipment of the electrical engineering laboratories and machine room has also been considerably extended and brought up to date. Calendar, containing particulars of all courses, on application to the director of education, Mr. A. C. Coffin.

University of Birmingham.—The session commences Oct. 2. The full courses extend over four years, and students who enter after matriculations and who pass successfully the examinations at the end of each year will be entitled to the degree of Bachelor of Science in the branch of engineering to which they devote themselves. The technical engineering classes are detailed, and a list of the professors, lecturers, &c., is given in an announcement on another page.

Northampton Polytechnic Institute, Clerkenwell, London.—The full day courses in the theory and practice of mechanical and electrical engineering, and in electro-chemistry will commence on Oct. 2, and entrance examinations will take place on Sept. 27 and 28, at which five entrance scholarships will be offered. The courses for mechanical and electrical engineering include periods spent in commercial workshops, and extend over four years, and they also prepare for the degree of B.Sc. in engineering of the University of London. There are also full and partial day courses in technical optics. Particulars from the Principal, Dr. R. Mullineux Walmsley.

University of Bristol.—Prospectuses and particulars of the faculties of arts, science, medicine and engineering (civil, mechanical, electrical and motor car) and of the secondary training department, day training colleges, evening classes, halls of residence, scholarships and bursaries will be sent on application to the registrar, Mr. James Rafter. The session in the faculty of engineering commences Sept. 15 and in faculties of arts, science and medicine on Oct. 2.

University of Liverpool.—The courses of study in the faculty of engineering, leading to the ordinary degree of B.Eng., extend over at least three years, and they are so arranged as to afford a general scientific training for those who intend to become engineers, naval architects or architects and surveyors. There is a two-years' course, leading to a certificate in engineering, for students who do not proceed to a degree, and in the honours schools students may specialise in some branch of the profession. Facilities for post-graduate and research work are also afforded in the honours schools.

South-Western Polytechnic Institute.—This institute provides a complete three-years' course, leading to a diploma or university degree, in electrical engineering. A four-years' course is held in the evening. Separate courses of lectures and practical work are given in elementary, intermediate and advanced electrical engineering, electrical design, a.c. and polyphase currents, wiring and fitting, &c. Particulars from the Secretary, Manresa-road, Chelsea, S.W.

ARRANGEMENTS FOR THE WEEK.

BRITISH ASSOCIATION.

Wednesday, August 30th.

Meeting at Portsmouth. Presidential Address by Sir Wm. Ramsay K.C.B., F.R.S.

Thursday, August 31st.

Addresses by the Presidents of the Various Sections. To Section A (Mathematical and Physical Sciences) by Prof. H. H. Turner. To Section G (Engineering) by Prof. J. H. Biles. To Section L (Educational Science) by the Right Rev. Bishop J. E. C. Welldon.

A list of the various Papers to be read during the meeting, which lasts until Wednesday, September 6, was given in our issues of July 21 (p. 572) and July 28 (p. 612). The actual days on which these Papers will be read will only be announced at the meetings.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued :—

Head-quarters will be closed for instruction, but will be open for office work as under until further orders :—

Monday to Friday, 10 a.m. to 4 p.m.
Saturday, 10 a.m. to 12 noon.

Digitized by Google

GLASGOW CORPORATION TRAMWAYS.

During the last few years the revenue of these tramways has been practically stationary, but for the year ended May 31 last the normal development seems again to have been resumed. Thus, the receipts which a year ago were £896,720, compared with £892,751 in 1908-9, have risen to £949,489, an increase of £52,769. As the working expenses only rose by £30,268 to £533,179, it will be seen that a larger profit had to be dealt with. This resulted in a greater contribution to the "Common Good," viz., £68,678 as against £53,028 in the previous year, and this Fund has now benefited to the extent of £448,466 since 1894. It may be noted that by section 30 of the Glasgow Corpn. Act, 1909, any surplus remaining after payment of working expenses, interest, sinking fund and depreciation is to be handed over to the "Common Good," to be applied at the discretion of the Corporation.

The number of car-miles run during the year was 21,704,237, compared with 20,974,016 in 1909-10, the corresponding receipts per car-mile being 10·46d. and 10·22d. respectively.

The total number of passengers was 237,967,307—an increase of 15,236,736—and the number carried at each fare was as follows :—

Fare.	Number.	Per cent
½d.	66,290,055	27·86
1st two stage	5,573,508	4·61
2nd two stage	5,398,884	
1d.	130,519,231	54·85
1½d.	19,408,739	8·15
2d.	5,879,305	2·47
2½d.	2,453,123	1·03
3d. and above	2,444,462	1·03
	237,967,307	100·00

The average number of journeys per head of population per annum was 206·9, as against 184 journeys per head of population at Manchester (*See* THE ELECTRICIAN, August 11, 1911, p. 693).

In view of the prosperity of their tramways it is not surprising that the Corporation have been able to make certain concessions to passengers. Thus, from January 1 last all children up to 15 years of age are charged half fare. Free travelling facilities are also given to all blind persons resident in the city (it is estimated that this concession will cost £550 per annum). The Corporation are also experimenting with two-stage 1½d. tickets. These entitle passengers to travel two consecutive ½d. stages on one car, and another two consecutive ½d. stages on a second car. An increased scale of wages for motormen, conductors, cleaners, labourers, &c., came into force as from June 1, 1911.

The stock of cars at May 31 was 803, whilst 50 cars are under construction. The cars at present in use comprise 621 with top covers, 71 standard cars, 110 converted horse cars and 1 school car. The Tramways Committee have decided to fit covers on all cars with the exception of the converted horse cars. The experiments with the use of vestibules having been found satisfactory, the Committee have decided to equip all the cars with a suitable vestibule in order to protect the motormen during inclement weather.

The total length of single track in operation at May 31 was 96½ miles, excluding depot connections, crossings, &c. Of this total, 2 miles were in Paisley over which the Corporation have running powers, whilst 8¾ miles are leased from the Corporation of Govan.

It is interesting to notice that the use of meters on the cars has been under consideration, and a number of meters are being installed. In this connection we may mention that the total number of units used per car-mile for traction and car lighting was 1·31, as against 1·28 in 1909-10, and 1·25 in 1908-9; the total number of units used on the cars was 28,345,441. It will be remembered that the tramway undertaking possesses its own power station, and the power expenses are stated as follows, the cost per unit being based on the number of units sent out from the power station to the sub-stations, viz., 30,298,917.

		Cost per unit sent out.
Salaries and wages	£11,425	0·09d.
Fuel	16,595	0·13d.
Oil, waste, water, &c.	2,496	0·02d.
Repairs to steam plant	2,829	0·02d.
,, electrical plant	1,679	0·01d.
,, ducts, feeders, &c.	3,663	0·03d.
,, station buildings	1,287	0·01d.
	£39,974	0·31d.
Proportion of rents, rates and taxes	£6,384	0·05d.
,, insurance	333	0·00d.
,, management	1,000	0·01d.
Depreciation	58,935	0·47d.
Interest	18,312	0·15d.
Sinking fund	22,979	0·18d.
	£147,917	1·17d

With reference to the basis on which the above figures are determined, the following particulars as to the output are of interest :—

Units generated—		
Alternating current		30,649,600
Direct current (500 volts)		813,997
Direct current (100 volts)		199,561
Total units generated		31,663,158
Used at power station		1,364,241
Total sent out to sub-stations		30,298,917
Used in sub-stations	257,517	
Used in depots, &c.	1,596,808	
Estimated loss	99,151	
Total supplied for traction load		28,345,441
Loss in conversion and transmission		1,437,791
Supplied from d.c. 'bus-bars		26,907,650
Maximum load on power station		9,100 kw.
Load factor		39·7 %
Coal per unit generated		2·88 lbs.

We give below an analysis of the Accounts for the whole tramway undertaking for the 12 months ended May 31, 1911, together with the cost per car-mile of each item. The corresponding figures per car-mile for the previous year are also included.

		Cost per car-mile. 1910-11.	1909-10.
Traffic Expenses.			
Superintendence	£5,531	0·06d.	0·06d.
Wages of motormen and conductors	191,587	2·12d.	2·14d.
,, other traffic employés	11,668	0·13d.	0·14d.
Motormen's bonus	3,096	0·03d.	0·04d.
Cleaning and oiling cars	31,657	0·35d.	0·32d.
Cleaning track	4,495	0·05d.	0·06d.
Fuel, light and water for depots	2,559	0·03d.	0·03d.
Ticket check	10,957	0·12d.	0·12d.
Uniforms	6,377	0·07d.	0·09d.
Miscellaneous	2,865	0·03d.	0·04d.
Total Traffic Expenses	£270,792	2·99d.	3·04d.
General Expenses.			
Salaries and wages	£7,444	0.08d.	0·08d.
Store expenses	961	0·01d.	0'01d.
Rents, &c.	4,160	0·05d.	0·04d.
Rates and taxes	61,025	0·68d.	0·71d.
Printing and stationery	1,985	0·02d.	0·02d.
Fuel, light and water for offices	421	0·00d.	0·01d.
Law expenses	529	0·01d.	0·00d.
Insurance	21,449	0·24d.	0·24d.
Parliamentary expenses	40	0·00d.	0·00d.
Deputation and travelling expenses	372	0·00d.	0·00d.
Miscellaneous	6,659	0·07d.	0·06d.
Total General Expenses	£105,045	1·16d.	1·17d.
Repairs and Maintenance.			
Permanent way	£55,248	0·61d.	0·46d.
Electrical equipment of line	8,368	0·09d.	0·08d.
Buildings and fixtures	6,864	0·08d.	0·05d.
Workshop tools, &c.	1,003	0·01d.	0·01d.
Cars	26,742	0·30d.	0·30d.
Electrical equipment of cars	19,450	0·21d.	0·21d.
Other rolling stock	1,768	0·02d.	0·03d.
Miscellaneous —	140	0·00d.	0·00d.
Total Repairs and Maintenance	£119,583	1·33d.	1·14d.

Digitized by Google

		Cost per car-mile. 1910-11.	1909-10.
Power Expenses	£37,759	0·42d.	0·41d.
TOTAL WORKING EXPENSES (*ex.* capital charges, &c.)	**£533,179**	**5·90d.**	**5·76d.**
Capital Charges, &c.			
Rental of leased lines	£10,027	0·11d.	0·11d.
Interest	75,168	0·83d.	0·83d.
Sinking fund	89,794	0·99d.	0·97d.
Income tax	13,492	0·15d.	0·18d.
Parliamentary expenses ("Common Good")	15	0·00d.	0·02d.
Depreciation and renewals	202,579	2·24d.	2·22d.
Total Capital Charges, &c.	**£391,075**	**4·32d.**	**4·33d.**
TOTAL EXPENSES (*inc.* capital charges)	**£924,254**	**10·22d.**	**10·09d.**
Revenue.			
Traffic revenue	£946,021	10·46d.	10·23d.
Rents and dues	2,854	0·03d.	0·03d.
Sale of electrical energy	613	0·01d.	0·01d.
Interest on investments	43,214	0·48d.	0·43d.
Lines rented to Dumbarton Tramways	230	0·00d.	0·00d.
TOTAL REVENUE	**£992,932**	**10·98d.**	**10·70d.**
Balance	£68,678	0·76d.	0·61d.

This surplus, as mentioned above, goes to the "Common Good."

A feature of the Accounts is the large contribution for depreciation and renewals. The method on which this sum is arrived at was given in our analysis of last year's Accounts (THE ELECTRICIAN, November 4, 1910). The Depreciation and Permanent Way Renewals Fund now stands at £1,702,915, whilst the General Reserve Fund balance is £50,832.

The gross capital expenditure at May 31, 1911, was £3,921,407. Of this total, £2,121,147 had been written off and set aside for depreciation at that date. The various items comprised in the above expenditure are as follows :—

	Gross amount.	Net amount.
Permanent way	£1,104,791	£562,860
Electrical equipment of line	722,324	403,809
Ground	168,497	165,751
Buildings, &c.	557,719	293,232
Power station and sub-station plant	459,971	168,680
Tools, &c.	37,896	10,177
Electric cars	507,660	181,285
Horse cars	54,192	—
Horses	250,786	1,636
Other rolling stock	16,189	5,256
Office furniture	6,593	329
Lease of Govan and Ibrox Tramways	4,057	3,011
Miscellaneous	30,731	4,233
	£3,921,406	£1,800,259

THE DEVELOPMENT OF THE METALLIC FILAMENT.*

BY DR. MONASCH.

The first tungsten lamp was exhibited in Germany at the annual meeting of the Verband Deutscher Elektrotechniker in May, 1906. It was at once seen that a great change was impending, though the new lamp had at that time many obvious defects ; among these were its fragility, its cost, and the fact that the smallest size that was then possible was too large for domestic purposes. Thus the 40 c.p. lamp for 110 volts was composed of long loose loops, which had to be maintained in a vertical position, and which were little adapted to withstand the rough usage of transport.

New ideas are generally regarded with suspicion ; but in this instance the reverse was the case, and countless persons busied themselves with the problem of turning out a marketable product that should take 1·1 watts per candle-power, and should burn for 1,000 hours ; factories which had hitherto turned out carbon filaments took the matter in hand, and many competitors arose, starting with much too little capital, many of whom have since disappeared. All sorts of fancy trade names began to be attached to the various products ; and for 100 volts, lamps are now to be had ranging from 16 to 1,000 c.p. and a very nearly similar range for 250 volts. All these lamps can be suspended in any position ; but mechanically they are, of course, not so strong as the old carbon filaments, since they are much longer and thinner, and at the same time made of a more brittle substance. Still, cases are known where these lamps are giving satisfaction even when exposed to regular periodic shocks or vibrations.

Naturally enough the problems to be solved were very difficult. Apart from the construction of the filament itself, most of the questions that arose were of a mechanical nature. Instead of a series of freely hanging loops, it was soon found advisable to anchor them at various points. The materials of which these anchors were to be composed led to an exhaustive test of almost every substance under the sun. Gradually a sort of normal construction became more or less standardised, with short loops, a kind of springy grip, and a central glass support for the whole.

In 1906 there were general complaints that 16 c.p. lamps seemed out of the question, but these were put on the market for 110 volts in 1909, and there seems nothing in principle to prevent the manufacture of similar lamps for 10 c.p. But the makers take little interest in the latter problem, partly because the sphere of usefulness of such lamps is actually very limited, and partly because the demand for the higher powers is so great that there is some little difficulty in meeting it. When lamps took 3·5 watts per candle-power, the 10 c.p. lamp may have been needed ; but they were generally used in places where they were very infrequently alight, and took more current than a 25 c.p. tungsten lamp, which has to all intents replaced it. An increasing desire for comfort makes one desire to see clearly rather than dimly, and it is nearly time for the total abolition of the 10 c.p. lamp, which hardly suits modern requirements and possibilities.

On the other hand, the tungsten lamp has invaded the sphere of the arc lamp. Normally carbon lamps were made up to 50 c.p. A lamp giving 100 c.p. would take 350 watts, which is as much as a 6-ampere arc lamp. But with 1-watt lamps things are quite different. Remané showed at Erfurt that the high candle-power tungsten lamps were more economical than open alternate-current arc lamps. With direct current they were superior to those of the Jandus type taking three amperes, but with larger currents the advantage lay with the arc lamp. In spite of this, the tungsten lamp has in the course of time displaced many an arc lamp owing to the ease with which it can be used ; there is no need for attendance, no store of carbons has to be kept, and there is no regulating mechanism to get out of order. It can therefore be said that the tungsten lamp is used up to 1,000 c.p. nowadays, while anything beyond this is allotted to the arc lamp.

In the practical application of the lamp, many curious phenomena were observed. If considerable groups of lamps were switched on at once, the fuses often blew without any apparent reason. The oscillograph, however, showed that at the moment of starting, the tungsten lamp takes seven or eight times as much current as the normal, while the tantalum lamp takes four or six times, and the carbon lamp only 0·7 times the normal current. This is, of course, explained by facts relating to the resistances of the filament when cold and hot, the newer lamps having the ordinary properties of metals. The tantalum lamp is made of a drawn wire, and its peculiarities on alternating current are well known ; inter-molecular actions go on, the wire becomes crystalline, the molecules become displaced with regard to one another, and the whole shape of the wire becomes irregular. It was supposed in the first instance that the same thing would happen with the tungsten lamp. But this has not turned out to be the case. Tungsten lamps are composed of sintered particles, and experience has shown that if the filaments are properly anchored, they are capable of burning for 2,000 hours on alternating current. There is therefore practically little difference between alternating and direct current. Lately tungsten lamps have been made in America out of a drawn tungsten wire, and this type of lamp certainly shows the same peculiarities as the tantalum lamp, and the same changes of molecular structure on alternating current.

On alternating current there are other effects that are certainly very apt to be fatal to the lamps. An increase of voltage is very injurious, and shocks due to variations of voltage may destroy a lamp at once. Kinsloe has lately investigated some matters in regard to this. He examined the influence of the shape of the voltage-wave on the life and specific efficiency of the lamp. It has usually been assumed that the candle-power, efficiency, and life of the lamps depend on the mean effective value of the voltage, and are independent of its maximum value. Kinsloe ran a number of lamps on 110 volts, with a sine-wave, giving a maximum of 155 ; and others, also on 110 volts, with a very peaked wave which had a maximum of 174. He found that the carbon, tantalum and tungsten lamps had shorter lives and lower candle-power on the peaky voltage, and microscopic examination showed a greater tendency in this case to changes of structure and to become brittle. These results seem very important, and it is much to be desired that they should be further examined by other experimenters.

Another question relating to the use of tungsten lamps on alternating current is not without interest, and this is whether they can be used with a frequency of 25. A carbon lamp burns well without flickering under these conditions, and a frequency of 25 is gradually coming into extended use on railways. American investigators report that a 25 c.p. metal lamp flickers intolerably on 110 volts with this frequency; with a frequency of 40, there is still a notable flicker, which however disappears with a 50 c.p. lamp. This result is naturally to be expected, for the higher the candle-power, the thicker the filament becomes and the greater is its heat capacity; it will therefore cool more slowly during the fluctuations of the current, and its light will be more steady. Merrill has found that there is a critical frequency at which flickering begins, and this critical frequency can be considered to be a function of the product of the mean illumination and of the percentage variation of the illumination. The question as to whether a lamp flickers depends therefore largely on the mean value of the illumination. If we want to judge the flickering of lamps on a given low frequency, and concentrate our attention on any considerable surface illuminated by the light, the flickering always appears less if the distance between the lamp and the illuminated surface is increased, till finally, with a dim kind of lighted surface, the flickering seems entirely to disappear. This is due to some peculiar property of the eye, and might make it possible to use tungsten lamps on a low frequency, provided the illumination required on any particular surface is not high.

THE COMMERCIAL LOADING OF TELEPHONE CIRCUITS IN THE BELL SYSTEM.*

BY BANCROFT GHERARDI.

Summary.—The author first describes the method of loading underground telephone cables and the precautions necessary to minimise losses. He then refers to the New York–Philadelphia cable with heavy loading, and the results that have been obtained. Overhead lines are next considered, and finally the loading of submarine cables.

Before describing some of the practical applications of loading to open-wire lines and cables, the author mentions briefly the results of the fundamental work on this question.

The problem of loading underground cables is as a whole easier than that of loading open-wire lines and is, therefore, first discussed. At the present time we are making very general use of two styles of

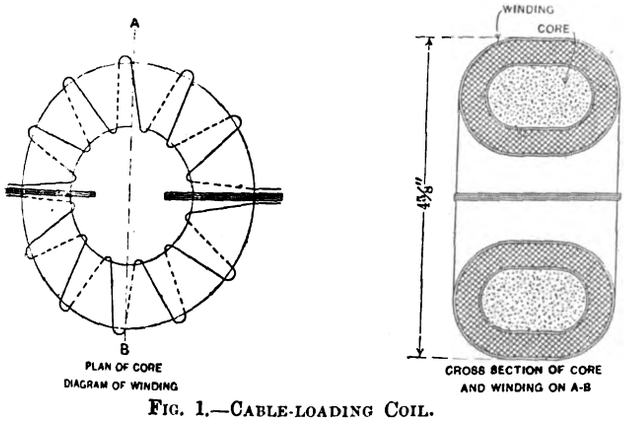

FIG. 1.—CABLE-LOADING COIL.

loading for telephone cables, one of which is characterised as "medium" loading and the other "heavy" loading. In a few cases a third style of loading, known as "light" loading, is employed. These three styles of loading differ in the amount of inductance placed upon the lines, and hence in the improvement in transmission obtained from the loading. The heavy loading, as the term would suggest, places the greatest amount of inductance on the line and requires coils placed at closer intervals. This heavy loading employs about 0·2 henry per mile and the spacing between coils is about 1¼ miles; medium loading provides 0·1 henry per mile with the coil spacing of about 1¾ miles; light loading employs 0·05 henry per mile with a spacing of about 2½ miles. The coils of these various loadings are made up on similar cores, so that the coils differ only in reference to the windings placed thereon.

A description of the coil employed for medium loading and the method of applying it to the lines is as follows:—The coil is of the toroidal type, that is, it has an iron core like a ring. Fig. 1 shows a cable coil. The coil is made up of very fine iron wires. Two copper windings are placed on the core, one to go on each side of the line. These windings are also indicated in Fig. 2 which shows the way the coils are connected in to the line. The windings magnetise the core in the same direction, that is, the mutual induction is added to the self-induction. Over these windings there is placed a layer of tape for mechanical protection, and the whole coil is then thoroughly dried and immersed in compound to keep out moisture.

Before leaving the design of the coil it is interesting to consider the precautions which are taken to reduce losses in it. The first loss to be considered is a dissipation loss resulting from the resistance of the copper winding of the loading coil itself. This loss cannot be entirely eliminated, but it may be reduced as much as may be desired by increasing the cross-section of the winding. There are, however, practical limits to this, as the increase in the size of the winding increases all the mechanical dimensions of the coil and also tends to increase certain other losses. A second possible loss in loading coils may also develop in the copper winding. If the cross-section of the conductor used for winding the coil is large, eddy currents may form within the conductor itself and these would produce substantial losses. Practically this factor is small in cable loading coils, but in open-wire coils where a conductor of greater cross-section must be employed it has been found necessary to strand this conductor and to insulate the various strands from each other.

In the iron core of the loading coil there are also several possible losses. In the first place, there is the hysteresis loss. After a great deal of work it has been found practicable to obtain special grades of iron which, when worked within certain limits of magnetisation, are substantially free from hysteresis losses. This at once imposes a limitation on the design of the loading coil and affects the proportioning of all of its parts.

Another loss which may take place in the core of a loading coil is that due to eddy or Foucault currents which may develop in the material of the core itself. In the case of loading coils it has been necessary to construct the cores of extremely fine wire and to coat this wire with a film of insulating material.

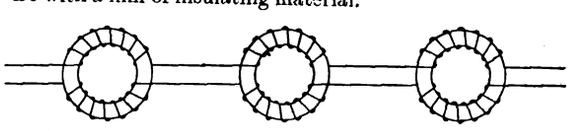

FIG. 2.—DIAGRAM OF LOADING COIL WINDINGS AND METHOD OF CONNECTING INTO A LINE.

Certain other losses also must be guarded against. If a loading coil when magnetised gave an external magnetic field and there were any conducting materials in this field, eddy currents would be produced in this conducting field and would represent a loss of energy through the circuit. Similarly, if there were any iron or other magnetic substances in this field there would be likely to be hysteresis losses in this iron. These losses have been guarded against by adopting the toroidal form of coil already described and placing the windings on it in such a manner that practically no external magnetic field is in any case produced. The designing of loading coils in this manner has not only eliminated external losses but makes it possible to place loading coils in close proximity to each other without introducing cross talk between the circuits involved.

The direct current resistance of the medium-loading coil is about 4 ohms. The alternating current resistance of this coil at a frequency of about 800 periods a second is about nine ohms. This relatively small increase of resistance at such a high frequency is a good indication of the skilful design and careful manufacture of these coils.

The results obtained by applying medium loading to No. 19 B. & S. gauge underground cable, having a capacity of about 0·070mfd. per mile, are shown in Fig. 3. In this figure is also shown the transmission efficiency of the unloaded cable. These transmission efficiences are measured in terms of what we call standard No. 19 gauge cable. This standard is cable having a resistance of 88 ohms per loop mile and a mutual capacity of 0·054 mfd. per mile.

The efficiencies of the loaded circuits, shown in Fig. 3, are those obtained with sub-station instruments located directly at the ends of the loaded circuits. One curve is given showing the results obtained by the use of terminal transformers and the other without the use of such devices. These curves bring out clearly a peculiarity of loaded circuits which should be considered at this point. The loading of a circuit, either underground or aerial, brings in at the ends of the loaded circuit, whether the circuit is connected directly to sub-station instruments or to unloaded circuits, an effect which we have called reflection losses. That is to say, at the ends of the loaded circuit there are certain losses which take place which are substantially independent of the length of the loaded circuit involved. These losses as between loaded and unloaded circuits are dependent upon

* Abstract of a Paper read before the American Institute of Electrical Engineers.

Digitized by Google

the relative electrical characteristics of the loaded and unloaded circuits. In the case of sub-station instruments, connected directly to the ends of a loaded circuit, the terminal losses are dependent upon the relative electrical characteristics of the sub-station instrument and of the loaded line. Terminal or reflection losses, of course, also exist between unloaded lines of different characteristics, for instance, as between unloaded underground cable and unloaded aerial lines. They would also be found between sub-station instruments and unloaded lines of various kinds. In all these cases, however, they are small in magnitude and it is only in the case of loaded lines that they assume such proportions that they must be given consideration in connection with general engineering.

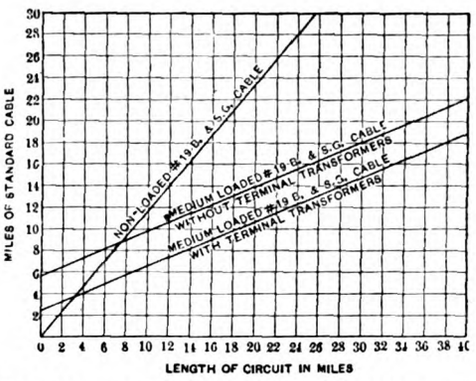

FIG. 3.—EFFICIENCY OF NO. 19 B. & S. GAUGE CABLE, UNLOADED AND MEDIUM LOADED, WITH SUB-STATION APPARATUS LOCATED DIRECTLY AT THE ENDS OF THE CIRCUITS.

I have been speaking of the terminal losses observed in connection with loading as though they pertained particularly to the loaded line. It has been convenient so to speak of them, but, of course, they actually pertain to the combination of loaded lines with unloaded lines or standard sub-station equipment, and properly are no more associated with one than with the other, but rather result from a combination of the two.

Various devices have been successfully employed to reduce terminal losses, although no plan has been worked out which would completely eliminate them. The plan used most successfully to-day for eliminating terminal losses is a device known as a terminal transformer. This is a transformer or repeating coil which differs from the standard telephone repeating coil in that there are more turns on one winding than on the other. It is used in the same

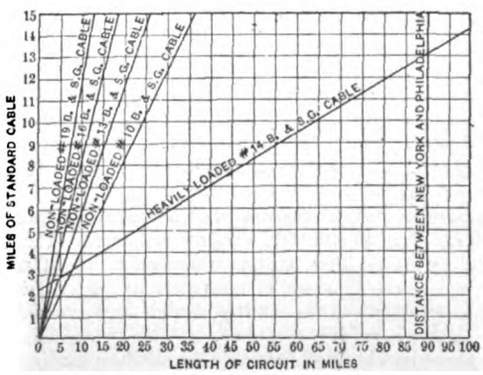

FIG. 4.—EFFICIENCY OF NO. 14 B. & S. GAUGE CABLE WITH HEAVY LOADING (NEW YORK–PHILADELPHIA CABLE); TERMINAL LOSSES WITH TERMINAL TRANSFORMERS AND ONE MILE LOOP; ALSO UNLOADED CABLES OF VARIOUS GAUGES.

way as an ordinary transformer in electric light practice, the high potential side being connected with the loaded line and the low potential side with the unloaded line. For ordinary conditions of loading the ratio of the two windings is usually either 1 : 1·4 or 1 : 2. The effect of the terminal transformer in reducing terminal losses is well shown in Fig. 3. The terminal loss for the two ends of a medium loaded line without terminal transformers is about 5·75 miles of standard cable. With terminal transformers this is reduced to 2·5 miles. These figures are for cases where the telephone sub-station apparatus is located directly at the ends of the loaded line. Where, between the loaded line and the sub-station apparatus, there is a length of unloaded line it is found that terminal losses are not so great as if the terminal apparatus were directly at the ends of the loaded line.

While terminal losses are substantially independent of the length of the loaded line, they are affected by the character of the loading of the line. The heavier the loading the greater the reflection losses. While with medium loading the reflection losses, with no unloaded cable at the ends of the circuit are 5·75 miles without terminal transformers and 2·5 miles with terminal transformers, the corresponding figures for heavy loading are 7·8 miles and 3·5 miles. These figures are, of course, reduced as in the case of medium loading, by having unloaded cable at the ends of the loaded circuit.

If it were not for these terminal losses it would be practicable, theoretically at any rate, to increase indefinitely the efficiency of a 19 gauge circuit by adding more and more inductance to it. Even without terminal losses, however, this could not practically be done, because more and more loading coils would have to be added as more inductance was added, and these would in turn bring in larger and larger losses, until finally the further gains from adding inductance would be offset or more than offset by coil losses. The increasing effect of leakage as the weight of loading is increased also has a limiting effect. Aside from these effects, terminal losses, which increase as the amount of inductance added to the circuit is increased, place a limitation beyond which it is not advantageous to increase the amount of loading on the circuits.

For underground circuits requiring a greater transmission efficiency than can be obtained by the use of heavily loaded 19 gauge cable circuits, it has been found best, all things considered, to employ a larger gauge of wire rather than to load more heavily. Many cables containing 16, 14, and 13 B. & S. gauge conductors have been laid and loaded.

The most interesting existing cable containing large gauge conductors is the New York–Philadelphia cable which was laid several years ago between these two points in order to provide additional circuits and to insure the service against storm damage. Most of the circuits in this cable are 14 B. & S. gauge and they are heavily loaded. That is, there is 0·2 henry per mile added to the cable

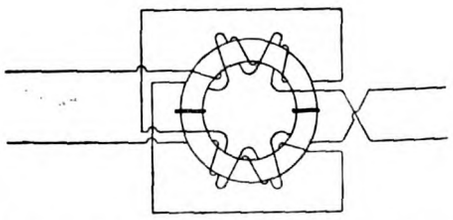

FIG. 5.—DIAGRAM OF WINDING OF LOADING COIL FOR CIRCUITS FORMING THE SIDES OF PHANTOM.

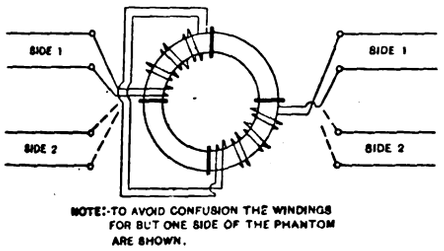
circuits by means of loading coils. The results obtained on these circuits are given in Fig. 4, assuming average terminal conditions. The results obtained by this loading are most satisfactory. The distance between New York and Philadelphia, following the route of the cable, is 90 miles. It will be seen that for this distance the circuits have an efficiency of 13 miles of standard cable. If unloaded, these circuits would have an efficiency of about 60 miles of standard cable. Over such circuits no commercial service could be given between New York and Philadelphia.

While this New York–Philadelphia cable represents the longest loaded underground cable to-day in use anywhere in the world, a project has been approved and is now under way which will far surpass it. This project is for an underground cable extending between New York and Washington in one direction and New York and Boston in the other. The largest conductors in this cable will be No. 10 B. & S. gauge and by means of loading we confidently expect that we will be able to obtain thoroughly satisfactorily results between New York and either Boston or Washington, and that it will even be possible to obtain service through this cable between Washington and Boston should storm-damage to the open wire lines render this necessary. The loading of this cable will be of particular interest as it will represent the first large application of the phantoming of loaded cable circuits and the loading of phantom cable circuits. In order to accomplish these results it is necessary to adopt special arrangements of the windings of the loading coils. The windings on the loading coil used for loading the side circuits are arranged as shown in Fig. 5. With this arrangement of winding, the effect of the telephone current in the side circuit, which current flows in opposite directions in the two sides of the circuit, is to magnetise the core of the loading coil in the same direction throughout and to produce no consequent poles. The loading coil thus acts, in so far as the side circuit is concerned, exactly like the loading coil with

Digitized by Google

the simple winding shown in Figs. 1 & 2. In building up a phantom circuit this side circuit, however, becomes one side of the phantom, and the telephone current in the phantom circuit traverses the two wires of the side circuit in parallel. Such a current flowing through the windings of such loading coils as are shown in Figs. 1 and 2 would magnetise the two sides of the core in opposite directions and produce consequent poles at the two sides of the core. This would not only bring in serious losses, but also cross talk which would be very difficult to deal with. The current in the phantom circuit flowing through a coil with windings on it as shown in Fig. 5 does not magnetise the loading coil at all, as each winding is neutralised by a corresponding winding on the other side of the line. Such coils may be used effectively to load the side circuits of a phantom combination and in as far as the phantom itself is concerned they act only as resistance which is very small in amount. This, however, does not load the phantom circuit, which of course is a desirable result to attain. To load the phantom circuit a coil with windings as shown in Fig. 6 is employed. It will be seen by tracing out the winding of this coil that to the current flowing in the phantom circuit it acts like an ordinary loading coil, that is, all windings magnetise the core in the same direction. To currents flowing in either side of the side circuits, however, it acts only as dead resistance. The arrangements described above in connection with the application of loading coils to phantom circuits and to the side circuits of phantom circuits have been successfully applied to open-wire lines as well as to underground cables.

Loading Open Wire Lines.—Gratifying as have been the results obtained from the use of loading on underground cables, its application to open-wire circuits has also resulted in most noteworthy improvements in their efficiency. The general plan of loading open-wire circuits is similar to that used on underground cable wires. On account of the differences in the electrical characteristics of open-wire circuits, as compared with cable circuits, however, the design and spacing of the loading coils is materially different from the coils and the spacings used on the underground cables. In general,



IG. 6.—DIAGRAM OF WINDING OF LOADING COIL FOR USE ON PHANTOM CIRCUITS.

ly heavy loading is used on open-wire lines on account of the reater length of these lines. The coils themselves are substantially rger than those employed on cable circuits for two reasons—in the st place the coil is subject to damage by lightning. In order to inimise this difficulty the coils must be built to have high break-wn strengths against lightning discharges. All aerial coils are ilt so that they will stand a breakdown test of 8,000 volts. This, course, considerably increases the size of the coil. The coil is rther increased in size by the fact that, as an aerial circuit is initially good deal more efficient than an underground circuit, it is neces-ry that the coils used in loading it should have smaller losses than re permissible in underground cable loading coils. The outside ameter of the aerial loading coil is about 10 inches and the resistance the two windings of the coil to direct current is 2·5 ohm, while to ternating currents of a frequency of 800 periods a second it is 5 ohm. In addition to building the coil so that it has a breakdown rength of 8,000 volts, each coil is protected by a pair of lightning resters adjusted to operate at 3,500 volts. These precautions ve proved sufficient to reduce trouble from lightning on aerial ading coils to a negligible amount.

Low insulation which is sometimes encountered on open-wire lines, rticularly in periods of bad weather, proved at the start a serious fficulty in connection with the loading of open-wire lines. This, owever, has been overcome by removing the worst causes of low sulation and in some cases by the use of improved insulators, and the present time low insulation is not proving a serious factor in nnection with the application of loading to overhead lines.

In connection with the loading of open-wire lines the problem arranging them so that they will be free from substantial cross lk has required attention. Due to the fact that much of the oss-talk disturbances in telephony are from electrostatic induction is to be expected, and it is found in practice, that the loading of a circuit increases its tendency to cross talk. In the early applications of loading to open-wire lines some trouble was experienced from cross talk and special transposition systems were devised to overcome these difficulties, and it was further found necessary to locate the loading coils with special reference to the transpositions. On underground cables it has been found that loading also increases the cross talk somewhat, and in these we arrange to reduce the capacity unbalances in order to reduce cross talk to a sufficiently low point.

The loading coils for use on open-wire circuits are placed in individual cast-iron cases and these are placed on the poles or crossarms. The line is carried to the loading coil by means of bridle wire. The lightning arrester is placed in a separate case and bridle wire is also extended to it.

The results obtained by the use of loading coils on the No. 8 B.W. and No. 12 N. B. S. gauge wires, which are the standard sizes used in the long distance plant of the Bell system, are shown in Fig. 7, in which for the purpose of comparison the efficiencies of the unloaded circuits are also given. This diagram shows terminal losses with the conditions which may be considered as average. The general reflection loss problem with overhead lines is the same as with underground cables, and has been discussed above. As will be seen from Fig. 7, the results obtained from loading open-wire lines have been more than to double their transmission efficiency when used in considerable lengths.

One of the very valuable results which has followed from the loading of open-wire lines has been that it has made a very substantial extension to the distance over which long distance service can be given. Up to the time that loading was successfully applied to No. 8 B. W. G. wires, about 1,000 miles represented the greatest distances over which commercial service was maintained. By the

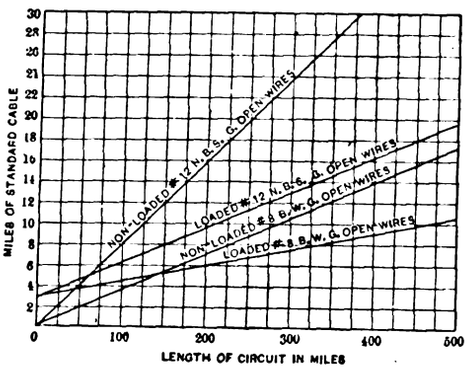


FIG. 7.—EFFICIENCY OF NO. 8 B.W.G. AND NO. 12 N.B.S.G. OPEN WIRE LINES, LOADED AND UNLOADED, WITH AVERAGE TERMINAL CONDITIONS.

loading of No. 8 circuits this has just been extended to 2,000 miles, so that to-day it is practicable to obtain a successful telephone conversation from New York to Denver. The actual distance between these two points by the route which the line follows is 2,010 miles.

A very important use has been made of loaded cables in bringing loaded open wire lines into large cities. Loaded cables have also been used to bring unloaded open-wire lines into thickly settled communities, but in this case the gains have not been so great because it is not practicable to place terminal transformers for reducing the reflection losses between the outer end of the underground cable circuits and the aerial lines, and hence reflection losses are experienced.

This practical impossibility of placing reflection reducing devices between open wire and cable has also made it impossible to obtain the full benefits from loading in those cases where short stretches of cable are placed in the middle of toll lines—*e.g.*, in communities where the appearance of the open wires is objected to and requests are made to place them underground.

Loading of Submarine Cables.—The problem of loading submarine cables is a mechanical one rather than one concerning the principles of loading. In this country a 16 B. S. & G. dry core paper submarine cable about 5 miles long and containing loading coils spaced about 2 miles apart has been successfully laid across Chesapeake Bay and is now in operation. There has also been talk of laying a dry core loaded submarine cable across Puget Sound for a distance of 16 miles. The situation in the United States, however, is not such that large numbers of loadeed submarine cables of any great length are required. Abroad, however, particularly between England and the continent and between England and Ireland, submarine cables of considerable length are needed for telephone purposes and in these situations loaded gutta-percha submarine cables have been employed with successful results.

Digitized by Google

Extent of Loading.—Although the loading art was born in 1900, and its successful commercial application on an extensive scale to our plant dates only from about 1903, there are already in the United States over 85,000 miles of loaded open-wire circuits and over 170,000 miles of loaded underground cable circuits.

Thus, the year 1900, in which the loading patents were issued to Prof. Pupin, marked the beginning of an important era in telephone work. I do not know of any problem in electrical science and electrical engineering which has required greater skill, technical ability and diligence on the part of those engaged in its solution, than has the working-out and the application of loading.

ELECTRIC STEEL PROCESSES AS COMPETITORS OF THE BESSEMER AND OPEN HEARTH.*

BY A. E. GREENE.

Electric furnace processes in steel manufacture have heretofore been largely used for the production of high-grade steel, and have not been considered competitors of the Bessemer and open-hearth processes for making ordinary grades of steel. The object of this Paper is to discuss certain characteristics of the processes commonly employed for making ordinary steel, and thus to lead up to the consideration of a new electric-furnace process which, by reason of improved economy of metal, bids fair to take a place of prominence in the development of a successful competitor to the Bessemer and open-hearth processes. The characteristics of these old processes to which attention is particularly called are the unavoidable losses of metal incident to such steel processes and the chemical reactions responsible for the great losses that occur. For instance in the Bessemer process alone in the United States, the loss of metal by undesired oxidation, vaporisation, &c., amounts according to some authorities, to half a million tons per annum, assuming a total production of ten million tons of Bessemer steel.

The chief advantage of the electric furnace does not consist simply in its ability to produce extremely high temperatures, but rather in the fact that it provides a means of maintaining a charge at any given temperature, thereby enabling one to control the composition of the atmosphere at will. This control enables us to accomplish hitherto unthought-of results. In this connection it will be of interest to consider for a moment the meaning of the term "neutral" as commonly applied to the atmosphere within furnaces in general, including electric furnaces. "Neutral" means inactive. But the atmosphere if of proper composition may react in such a way as greatly to aid a metallurgical process; for instance, the atmosphere in a steel-producing furnace might be reducing toward iron oxide and prevent the steel from oxidising; or it might be oxidising toward carbon or phosphorus and thereby eliminate them. Now, it is a most interesting fact that we can have an atmosphere which is reducing with respect to iron oxide and nevertheless oxidising toward carbon or toward phosphorus. The principle underlying that fact is the basis of a new process for oxidising carbon out of iron without oxidising the metal itself. The conditions under which such reactions might theoretically be carried out are well worth considering. If molten pig iron be placed in a closed crucible, made of magnesite for instance, and kept at a uniform high temperature, and the space above the iron in the closed crucible filled with CO_2 gas, the gas and iron will react and finally come to a state of equilibrium. The reaction might be represented as follows:

$$CO_2 + Fe = FeO + CO.$$

Under the equilibrium conditions which would be reached the ratio of the amounts of the two gases present would have a given value for the particular temperature. If we then replace the mixture of these two gases by another mixture containing relatively more CO and less CO_2 than the equilibrium mixture, and allow this new mixture to react with the iron and the iron oxide, some of the FeO would be reduced and the CO_2 component of the gas increased. This replacement could be made continuous by successive introductions of the new mixture. In this way reduction of iron oxide could be carried practically to completion, and moreover, this could be done by means of a gas containing an oxidising agent for carbon.

This was the theory on which the American Electric Smelting and Engineering Co. started in its experiments several years ago to develop a practical process for converting pig iron into steel and refining it without oxidising the iron and other valuable constituent metals. An extensive series of experiments has been carried out. The first experiments were made in small, electrically-heated magnesite crucibles, holding only a few pounds at a charge. Pig iron and various other metals were treated at different temperatures with various mixtures of oxidising and reducing gases for the purpose of ascertaining what ratio of reducing gas must be present to prevent oxidation. Almost pure CO_2 gas was used in some instances, and CO gas in others, and then various mixtures of such gases. It was found that a wide range of composition would still accomplish the desired results. It was found that producer gas might easily be made to serve the purpose, and that a producer gas containing as little as 4 per cent. of CO and as much as 15 per cent. of CO_2 would, when blown into molten pig iron at a temperature of about 1,450°C., eliminate the carbon with practically no oxidation of iron, manganese or silicon.

The process consists in providing in a 300-lb. induction furnace a bath of molten low-phosphorus pig iron containing, for example, the usual proportion of manganese, silicon and carbon. The charge preferably contains sufficient manganese and silicon to meet slightly more than the specification for the particular steel to be made. The temperature of the bath is raised to something over 1,425°C., which is maintained by the electric heating, while a gaseous mixture containing CO and CO_2 is blown into the metal in much the same way as air is blown into a Tropenas converter. This mixture may contain 12 to 18 per cent. of CO_2 and 5 per cent. or more of CO.

The rate of elimination is a little slower than with the Bessemer process for the same rate of blowing, but it was found that the gas could be blown into the metal without any formation of slag on the surface of the metal, and without any boiling. If an oxide slag had formed before the blow, as might happen when rusty scrap was melted to make up the charge, it was possible practically to completely reduce this iron oxide during the blow simultaneously with the removal of carbon. In this small furnace pig iron can be converted into steel with as small a loss of iron, manganese and silicon as 2·5 per cent., including losses in charging and spills in handling the steel. In view of the difficulty of handling molten steel in such small quantities as only 200 lb. without losing a few pounds this loss seems extremely low. In small Bessemer vessels holding as little as 300 lb. the loss of metal is said to be not less than 20 per cent., apart from the loss of weight by oxidation of carbon.

The most convincing evidence that oxidation does not take place in the process may be found in connection with the loss of manganese. In converting a 13·4 per cent. spiegel into manganese steel, we have done this without any additions of any kind, and have produced a steel containing over 12·5 per cent. manganese, and this was without the use of a slag to prevent vaporisation. The carbon was reduced from over 4 per cent. to 1·2 per cent. In later tests, using a lime slag, the vaporisation loss has been further diminished, and no difficulty is found in obtaining very low carbon manganese steel. The process can also be applied to making manganese steel from pig iron and manganese steel scrap. The power consumption need not be more than 500 kw.-hours per ton, and at a cost of 0·5d. per kilowatt-hour, the power cost would not amount to more than £1 per ton. The value of the manganese which can be saved is considerably in excess of this. Such application of the process as just described is suitable for utilising any kind of alloy steel scrap such as armour plate and tool steel scrap, not only cutting down losses and additions, but producing a higher grade of product.

The process described above for oxidising carbon without oxidising iron is similarly applicable to the removal of phosphorus. It is found that phosphorus can be oxidised out of iron and kept out by means of lime. This can be done with practically no oxidation of iron and manganese. It has been done at pig iron melting temperatures below 1,350°C. without oxidising the carbon, and at high temperatures, above 1,500°C., and up to 1,900°C. after the carbon has been oxidised. And beside the sulphur can be taken up and held in the same slag that holds the phosphorus. This action is attributed to the absence of oxide of iron in the slag.

A low-grade pig iron has been converted into a high-quality steel in one continuous operation in this way, taking out the carbon without oxidation of the iron and manganese and then, with a lime slag on top of the metal, by continuing the blow of the gaseous mixture, the phosphorus has been oxidised and eliminated. The phosphorus was found combined with the lime as calcium-phosphate, and practically all the sulphur was found in the slag as calcium-sulphide. Such a conversion of molten pig iron into refined molten steel has been carried out as just outlined in less than 30 minutes, which indicates that the reaction takes place quite rapidly and that the problem of installing the process in large vessels of 10 or more tons capacity is a mechanical one of getting the gas into the metal.

It may be of interest to compare the operation of making steel castings in a small plant using a side-blown Bessemer converter and in one fitted with an electric converter using the process described in this Paper. In the Bessemer plant, molten low-phosphorus pig iron is poured into the converter and blown until the carbon is practically out. The vessel is acid-lined and no phosphorus or sulphur can be

*Abstract of a Paper read before the American Electrochemical Society.

Digitized by Google

removed, so that the highest quality of iron must be used. This grade of iron usually contains about 2 per cent. of silicon and 0·5 to 1 per cent. of manganese. As already stated the total loss of weight during the conversion often averages 18 per cent., and as much as 12 or 13 per cent. of metallic iron may be oxidised. In a small plant recarbonising and deoxidising is usually done by adding ferro-manganese and ferro-silicon in the ladle, and even in this part of the process there is a further loss due to the oxidation of these alloys in entering the steel.

To get some idea of the value of the metal lost by oxidation, consider a small plant making, say, 20 tons of castings per day from 32 tons of molten steel and converting about 39 tons of molten pig iron per day to make the 32 tons of molten steel. Of the 7 tons loss, about 5 tons is metallic iron. The loss per year of 300 days would be 1,500 tons. If this metal had been saved as steel its value, at £6 per ton, would be £9,000. Such a loss is clear waste. Besides the iron there are other losses. Suppose the specifications require 0·60 per cent. of manganese; the cost of the 80 per cent. ferro-manganese required to give 0·60 per cent. manganese in the steel might easily be 1s. 10½d. per ton of steel or £864 per year. Practically one-third of the weight of ferro-manganese in the steel is lost in slag.

If it is possible to eliminate carbon without eliminating manganese it would be very simple to use a pig iron containing sufficient manganese to meet final steel specifications and not only would it be possible to dispense with the ferro-manganese additions costing about 1s. 10½d. per ton of steel, but the 0·6 per cent. of manganese saved would mean 0·6 per cent. more steel from the same weight of pig iron. It is by the saving of such metal that the increased cost of the electric-converter process will be much more than justified.

This electric converter process may be compared with the Bessemer process from two standpoints; first, assuming that only low phosphorus and low sulphur pig iron is used; and, second, assuming that impure iron is used. The programme of the electric-converter process for treating low phosphorus and low sulphur iron would be as follows: The molten pig iron is charged into a basic-lined electric converter. The type of converter which has most advantages for this purpose is an induction furnace having a main central hearth into the back side of which the tuyeres enter, and having two or more induction channels connecting with this main hearth.

The pig iron ordinarily would contain 1·5 per cent. of silicon and 0·75 per cent. to 0·85 per cent. of manganese. If low silicon iron could be readily had it would be so much the better for this process. But high silicon iron, which is more common, may be worked by the process, it merely involving the additional steps of lowering the content of silicon. Lime or limestone may be used for this purpose and is charged into the molten iron at the start. The metal, heated to about 1,450°C. is blown with a gaseous mixture which might well contain about 8 per cent. CO and 15 per cent. CO_2. The carbon is taken out until a fracture sample shows that the proper carbon remains. It is possible, by timing the blow to come very close to the desired percentage of carbon. The loss of manganese will be small enough so that the final percentage should not differ more than 0·05 or 0·10 per cent. from the percentage at the start. The silicon may be entirely removed or only in part. Finally any killing treatment desired may be given to the steel after the desired analysis is attained. In this process the oxidation loss of iron and manganese common in Bessemer practice can be almost entirely avoided.

The operation when high phosphorus and sulphur iron is used is quite similar to that just described. The raw material of course consists of low-grade iron. It is charged molten into the electric converter and lime is added to take up and hold the phosphorus and sulphur. In one method of operation the blow of gas is continued until practically all the carbon is oxidised and eliminated, a few tenths of 1 per cent. only remaining, and likewise until the silicon is practically all taken up by the lime, as calcium silicate. Continuation of this blow in the presence of the lime slag then takes out the phosphorus without formation of iron oxide. The interesting feature is that sulphur is also taken out and held out of the metal by that same slag. By this treatment the heavy loss of iron in the basic slag common to basic processes is avoided, and at the same time the slag is enabled to take up sulphur, which is in marked contrast with the basic process wherein the presence of iron oxide in the basic slag prevents such removal of sulphur to any great extent.

As compared with the combination process using a Bessemer converter and an electric furnace, the electric converter process presents several important advantages: First, the complete process is carried out in a single vessel thereby avoiding the inconvenience and loss of time, heat and metal contingent on transferring molten steel from one furnace to another and also avoiding the necessity of twice heating the same metal; second, the attractive feature of the basic Bessemer process, namely, the rapid elimination of phosphorus, may be taken advantage of without incurring its disadvantages in the loss of metal by oxidation and danger of over-blowing the steel; third, specially skilled operators are not essential to success of the process as there is no danger of over-blowing; fourth, high sulphur iron can be used, and this alone is a most important feature because of the large amounts of ore high in sulphur; fifth, the necessity of removing one slag and replacing it by another is avoided; sixth, the additions necessary in other processes are either greatly lessened or entirely avoided and also the losses attending those additions; and there are other advantages, among them being the ability to give the molten metal a killing treatment and to closely regulate its temperature all in one single furnace.

Little has been said in this Paper about furnaces. In the tests of this process various types have been used, including the induction type to which reference has already been made. The process is at present installed for test in a 2-ton furnace. The induction furnace has shown important advantages, in that it produces the heat where most heat is needed and does so without the heavy electrode cost attendant upon arc-furnace operation. In the operation of this process in large induction heated furnaces, we believe, that less than 30 kw.-hours per ton of steel will be required. This may sound very radical, yet when it is remembered that steel can be kept molten in induction furnaces at the present time with an expenditure of about 80 kw. of power per ton and that it has been possible to carry out the process of this Paper in less than one-third of an hour, the estimate is very reasonable. Such a low power consumption as 30 kw.-hours per ton, costing, at 0·25d. per kw.-hour, only 7½d. per ton, makes the use of electric heat assume an entirely different aspect in the development of a competitor of the converter or open-hearth furnace.

THE NEW PARIS UNDERGROUND RAILWAY.

THE NORTH-SOUTH LINE.

An electric subway, the North-South line, upon which the constructional work was begun several years ago, has recently been opened for traffic in Paris. Owing to the fact that it was from the start an entirely distinct enterprise from the Metropolitan Subway, the work was carried forward more rapidly

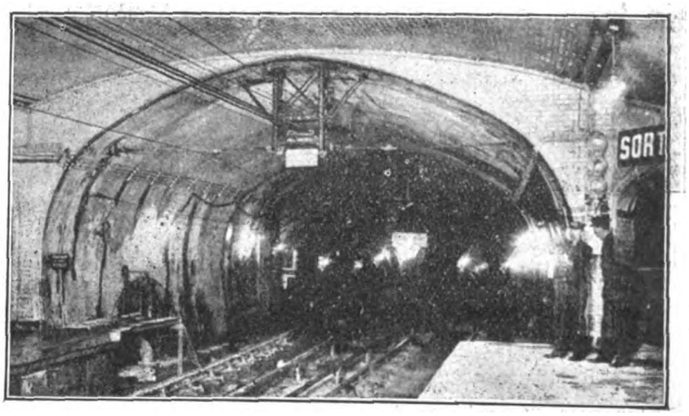

FIG. 1.—VIEW SHOWING OVERHEAD AND THIRD-RAIL CONSTRUCTION.

than would have been the case if it had been included in the present plans of the latter company. Our representative has had occasion to make several trips over the new subway since its official opening early in November last, and he informs us that the company appears to have taken great pains to introduce all the improvements made evident by the experience already acquired upon the other subway. Seeing that the line connects the southern quarter of Vaugirard with the northern Montmartre quarter, thus putting into direct communication the Montparnasse and the St. Lazare railway stations, it is likely to be well patronised. The double-track tunnel is of about the same dimensions as on the other system, with which there are four crossing points. Interchange stations allow the passengers to make a transfer between the two railways upon the same ticket. It will be remembered that where it crosses the Seine the line runs in a double iron cylinder, using two parallel single-track tubes. On the rest of the line, however, the standard elliptical section of tunnel is employed.

Digitized by Google

Motor cars and trailers of the same general appearance as those employed on the Metropolitan cars are also used on this line, though there are some differences in detail. One of the main differences in operating the trains lies in the use of the track rails as an earthed neutral conductor, and the employment of both a third rail and overhead trolley wire for supplying energy to the motors. In the case of two 600-volt direct-current motors, which is the standard equipment per train here as well as on the other subway, one motor is supplied from the third rail, returning to the track or earth, and the second from the trolley to earth, using 1,200 volts between the third rail and trolley. To keep the voltage constant at 600 volts on each motor the balance is maintained by the multiple unit control apparatus on the motor cars. As this does not allow the use of an uneven number of motor cars (three cars are sometimes used on the other line), the capacity of the motors is increased, so as to make them capable of drawing the maximum train load with two motor cars in all cases. Each motor car thus carries four motors, each of 125 H.P. The motors and controlling devices were built at the French Thomson-Houston Co.'s shops at Paris. Economy in wiring over the 600-volt system is secured by the use of a pressure of 1,200 volts, and there will be less earth leakage.

A special station did not have to be erected for the supply of current, seeing that this can readily be obtained either from the St. Denis or the Ivry stations in the suburbs. It is transmitted through underground cable to the two sub-stations of the subway as three-phase current, the pressure being from 10,000 to 15,000 volts. Each of the sub-stations is equipped

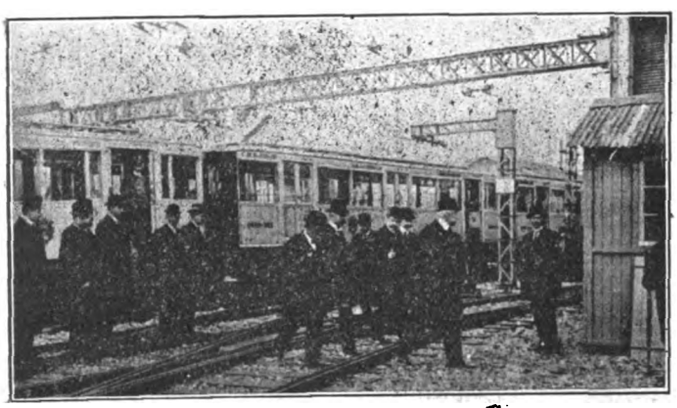

FIG. 2.—VIEW OF ONE OF THE TRAINS.

with transformers and rotary converters, whence 1,200 volts direct current is supplied to the line. Owing to the short length of the subway (9 miles) not more than two sub-stations were needed. There are at present 18 passenger stations opened for traffic between the Versailles Gate and a point somewhat beyond the St. Lazare station. The rest of the subway will be opened later on, and eventually there will be 31 stations. As before, the stations are of general elliptical section, with the two tracks lying in a depression between the station platforms. A white enamelled brick lining is used, picked out with coloured bricks. Two of the subway stations are worthy of note. One of these lies under the Rue de Vaugirard. It is built of reinforced concrete, as the narrow space between the house foundations did not allow masonry side walls to be used. Under the Place du Havre, in front of the St. Lazare station, a round underground hall, which did not figure in the original plans, has been built. The city of Paris gave a subsidy towards the cost of its construction, and it contains the ticket offices, news stands and a large circulating area. From here passengers can take different passages leading to the North-South or Metropolitan Railway, to the St. Lazare railway station or to the street.

First and second-class cars with about 80 places are used. They are mounted on double bogies in the case of both motor cars and trailers. The train is made up of a motor car at each end, together with a variable number, generally two or three, of ordinary cars. Special care has been paid to the illumination and ventilation of the cars. The ventilation is carried out through overhead openings. The motor cars differ from those on the other lines in the addition of a controller cabin at one end, otherwise the outside appearance and seating room is the same. The trains are run indifferently from one end or the other, so that there was no necessity for a loop to be built at the terminal stations.

As regards the financial and operating conditions of the Paris subways, it should be noted that the Metropolitan Co. is engaged in constructing a system of subways which is designed to cover the city as far as possible, and this work has been designed to be carried out in three parts, some of the lines being now completed while others are still under construction. When the whole of the plans are carried out there will be about 70 miles of Metropolitan lines. In the case of this system the tunnel work is carried out by the municipality and the tracks and wiring, &c., by the Metropolitan Co. But in the case of the North-South subway quite a separate arrangement was made with the city authorities, and the company undertook the whole of the construction work. Both subways will be taken over by the city after a period of 35 years, dating from the completion of the entire subway system. Our illustrations show a view of the tunnel with the overhead wires and third rail, and the general appearance of one of the trains.

THE METHOD OF CONSTANT RATE OF CHANGE OF FLUX AS A STANDARD FOR DETERMINING MAGNETISATION CURVES OF IRON.*

BY J. T. MORRIS AND T. H. LANGFORD, B.SC.

Summary.—An investigation is here described of the differences between the magnetisation curves for a given sample of iron when determined by the following methods: constant rate of change of flux, step-by-step method, method of reversals, and alternating current. The "uniformly varying flux" method appears to possess advantages over the older methods, and is recommended by the authors.

INTRODUCTION.

Doubts must have arisen in the minds of many investigators as to how nearly the magnetisation curves of a sample of iron obtained by different methods would agree with one another. Discrepancies which have been found from time to time may be attributed to:—(i.) Inaccuracies in experimenting; (ii.) Lack of exact repetition of previous conditions; (iii.) differences inherent in the methods employed.

The present research was instituted with the object of studying the last of these three causes, and obtaining definite information as to the magnitude of these differences (*a*) between the magnetisation curves for a given sample of iron when determined by the older methods, in which the flux is changed suddenly, and (*b*) by a method in which it is changed slowly and at a uniform rate.

The relation between the magnetising force H and the flux-density B produced by it in a specimen of magnetic material is usually determined by one of the following methods:—(*a*) Ballistic Methods; (*b*) Alternate-current Methods; (*c*) The "Fluxmeter"† Method; (*d*) Magnetometric Methods; (*e*) Attraction Permeameter Methods.

Permeameter measurements have the advantage of rapidity, but the accuracy attainable is not very high, owing to the indefinite degree of contact between the specimen and the yoke. This method is generally employed only for workshop tests. The magnetometric method is liable to inaccuracies due to the lack of uniformity in the magnetisation of the sample, including the indeterminate position of the poles and their demagnetising action. Alternate-current methods have the disadvantage that they are indirect, the required values of the current and flux-density having to be deduced from the observations by a complicated method if accuracy is to be ensured. When the greatest accuracy is required, ballistic methods on ring samples are, therefore, those to which resort is usually made. The test is commonly made by one of two methods. In one of these the current through the primary winding is increased up to a certain value and then suddenly reversed to obtain a reading; in the other method the current is increased or diminished by a step at a time,

* Abstract of a Paper read before the Physical Society. A brief account of the discussion that followed the reading of this Paper appeared in THE ELECTRICIAN for May 26, p. 258.

Digitized by Google

and the consequent ballistic reading taken. This difference in the character of the magnetic change to which the iron is subjected is liable to cause differences in the results obtained, partly owing to magnetic "creep" or viscosity.

A method proposed by C. F. Scott, and apparently first described by J. S. Peck,* as applied to large transformers, possesses the marked advantage over ballistic methods that the variation of the flux takes place at a known and constant rate, enabling experiments to be repeated under exactly similar conditions. Rates of change varying from 50 to 250 lines per square centimetre per second were actually employed in the experiments. Further, standardisation can be more readily performed, as a mutual induction is not required. This method has been modified by Dr. D. K. Morris so as to render it practicable for tests on small samples of iron.†

Method of "Constant Rate of Change of Flux."—Consider an iron ring in which a flux, N, is produced by a current, C, flowing in a primary winding. If the primary current be varied at such a rate that the induced E.M.F., E, in a secondary wiring is maintained at a constant value, the flux N is known to be varying at a constant rate, $dN/dt=k$.

In this case the total change of flux through the ring is simply proportional to the time during which it has taken place.

If n_2 be the number of turns on the secondary winding, and E be the value of the constant E.M.F. in volts induced therein, we have

$$E=dN/dt\times n_2+10^8=kn_2/10^8$$

and total change of flux $(N_2-N_1)=k(t_2-t_1)=E\times 10^8(t_2-t_1)In_2$.

Hence a magnetisation curve can be deduced from readings of current and time when the current is varied at such a rate that the secondary induced E.M.F. is constant and of known value. Since

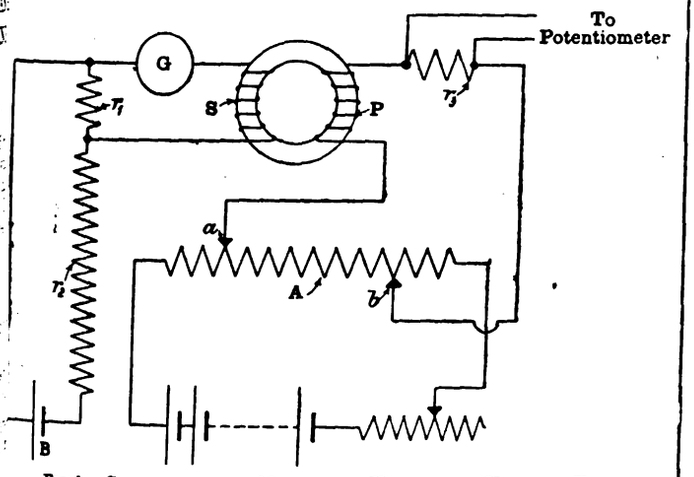

FIG. 1.—CONNECTIONS FOR METHOD OF UNIFORMLY VARYING FLUX.

the rate at which the flux is varied can be made as slow as desired, any "creep" in the magnetisation due to magnetic viscosity will be recorded. This method, therefore, appears to be preferable to others as the standard method for determining the fundamental magnetic properties of iron.

The following experiments were undertaken to investigate the differences, if any, between the results obtained by this and by other methods:—(I.) Method of constant Rate of Change of Flux, or, more shortly, that of "Uniformly-varying Flux" (or "Constant Induced Voltage," as it has been termed by previous writers). (II.) "Slow Cyclic" Hysteresis Loops. (III.) "Step-by-step" Magnetisation Curve. (IV.) "Step-by-step" Hysteresis Loops. (V.) Method of Reversals. (VI.) Alternating-current Magnetisation Curve. Before each reading recorded by methods (II.), (IV.) and (V.) the iron was brought into a cyclic condition by carrying it through a sufficient number of cycles of magnetising force of the same maximum value, some 50 cycles being generally sufficient for this purpose.

Method of uniformly varying Flux.—In Fig. 1 is given a diagram of connections. The voltage induced in the secondary winding S is balanced by the fall of potential over a known resistance, r_1, in series with a known resistance, r_2, across a cell, B, of known E.M.F., equality being indicated by a zero reading on a galvanometer, G. The battery B is closed on to the circuit r_1r_2, and simultaneously the primary current is caused to begin to change by means of the rheostat A, and the experimenter has continuously to adjust the rheostat at such a pace as will maintain the galvanometer reading at zero. This adjustment requires some skill, but an average experimenter easily acquires this with a little practice.

* "Electrical World and Engineer," Vol. XXXVII., p. 1,083, 1901.
† "Journal," I.E.E., Vol. XXXVII., pp. 282–294.

In making a hysteresis test the primary current is continuously varied from a maximum positive value to an equal negative value by a specially designed resistance,* in which two sliders, *a*, *b*, connected to the primary winding P, are moved in opposite directions across the edges of the zig-zag strip resistance A.

The primary current is measured on a potentiometer by the voltage drop across a known resistance, r_3, the exact times at which the current has certain convenient values being recorded by a chronographic arrangement.

The above electrical connections could be simplified if the galvanometer were directly closed on to the terminals of the secondary winding, but this arrangement has some objections—(1) that it is difficult to allow for the uncertainty in the value of the secondary E.M.F. induced during the time that the galvanometer deflection is attaining its normal magnitude; and (2) that a separate operation has to be performed in order to standardise the galvanometer. A further slight objection is that there is an opposing magnetomotive force due to the current flowing in the secondary winding. This, in general, however, is so small as to be negligible.

Data of Specimen used.—The ring was made up of 24 stampings, 6 in. external and 5 in. internal diameter, of Sankey's best transformer iron, manufactured about the year 1900, of 24 S.W.G. The mean magnetic length of the ring was found by measurement to be 43·93 cm. The sectional area of the ring was determined from its weight and specific gravity. The stampings were insulated from one another by thin paper rings, and the complete ring was lapped over

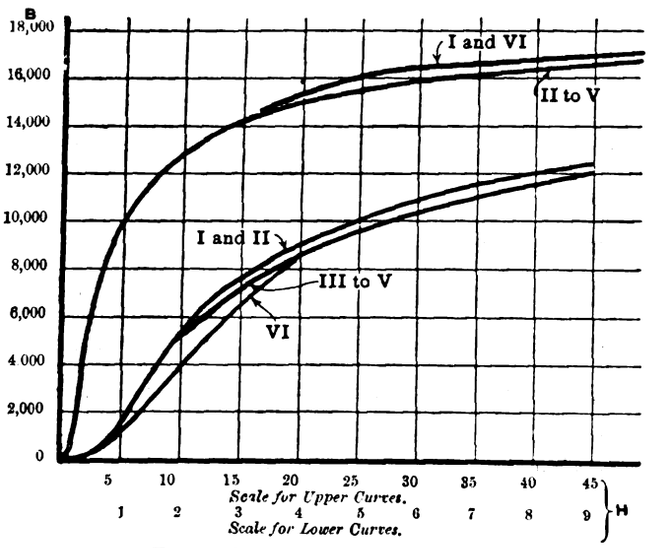

FIG. 2.—MAGNETISATION CURVES.

with insulating tape and wound with two No. 19 D.C.C. wires laid side by side, giving two windings of 147 turns each.

Experimental Results.—The results obtained experimentally by the above-described methods (I.) to (VI.) are given in the form of curves in Figs. 2, 3 and 4. The magnetisation curves are shown in Fig. 2, the initial parts being shown separately to an enlarged scale of H. In Fig. 3 the results are shown in the form of permeability curves, and in Fig. 4 in the form of reluctivity curves. In Fig. 5 the differences between the flux-density obtained by method (I.), and by methods (II.), (III.), (IV.) and (V.), with the same magnetising force, are plotted to a greatly enlarged scale against B as obtained by method (I.) The divergence of the magnetisation curve obtained by method (VI.) from the standard curve obtained by method (I.) is too great to allow of its being shown in Fig. 5, but is apparent in Figs. 2, 3 and 4.

Fig. 6 shows hysteresis loops taken by methods (II.) and (IV.), the maximum value of H being the same in each case.

The above experiments were carried out in the electrical engineering department of the East London College (University of London)

DISCUSSION OF RESULTS.

An examination of the divergencies shown in Fig. 5 has led the authors to divide, for purposes of consideration, the curves into three parts: (1) From zero to the approximate point of maximum permeability (B=5,000); (2) from this point to B=15,000; (3) above B=15,000.

Curves below B=5,000.—These may be divided into two groups: (*a*) Those in which the magnetisation curve is determined with the flux always changing in the same sense, the iron having previously

* J. T. Morris, R. M. Ellis and F. Stroude, "The Design of a Continuously Adjustable Rheostat," THE ELECTRICIAN, Vol. LXI., p. 400, 1908.

Digitized by Google

been completely demagnetised; and (*b*) those in which each reading is determined after the iron has been carried through a sufficiently large number of cycles of magnetising force to obtain constancy in the corresponding value of the flux-density.

Considering first those which belong to group (*a*), we have two cases: (i.) That of the magnetisation curve obtained by the uniformly varying flux method (method (I.)) and (ii.) the magnetisation curve determined by the step-by-step method (method (III.)) It will be noted in Fig. 5 that there is a difference between these two curves of, broadly speaking, some 250 lines per square centimetre, from $B=1,000$ to $B=12,500$, and that the step-by-step method is deficient by this amount. This difference appears to be due to some flux not

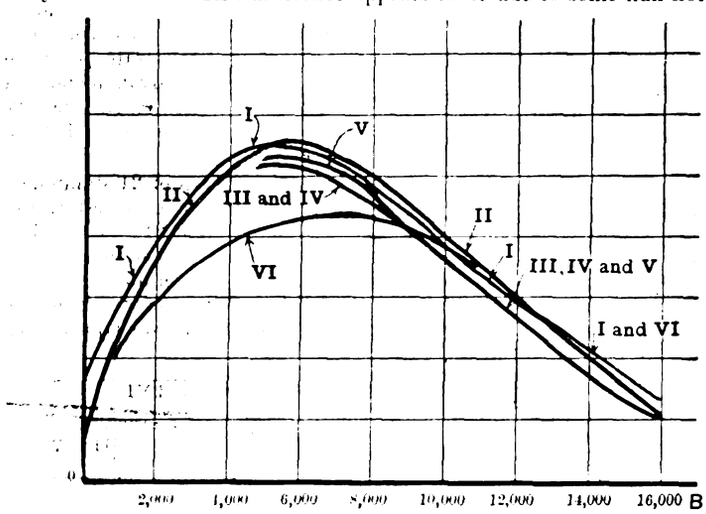

FIG. 3.—PERMEABILITY CURVES.

being recorded in the portion of the magnetisation curve below $B=500$ in the step-by-step method. It is quite probable that this is due to the known behaviour* of iron under weak magnetising forces. When a magnetising force of, say, $H=0{\cdot}2$ is suddenly applied, the flux at once changes by a certain amount and afterwards continues to change, though at a diminishing rate; this latter "creep" would not be recorded by an ordinary ballistic galvanometer, and therefore would not wholly be taken account of in the step-by-step method, but it is included in method (I.)—that of uniformly varying flux. (The time of one complete swing of the ballistic galvanometer used throughout these experiments was 8·6 seconds.)

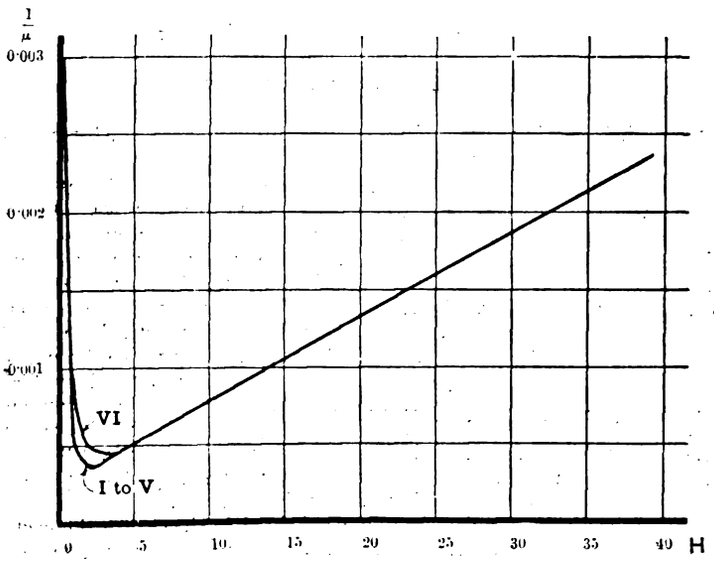

FIG. 4.—RELUCTIVITY CURVES.

Investigation of the amount of "creep" showed that this effect, although appreciable, does not appear to account wholly for the observed deficiency in the ballistic magnetisation curve. It will be noticed that all the curves in Fig. 5 start with a sharp downward inclination from the axis, showing that during the initial part of the magnetisation curve the highest value of B for a given value of H is attained by the method of uniformly varying flux, or, in other words, a higher value of H is required to produce the same observed value of B by the other methods. One reason for this may be that when the flux is changed suddenly, as in ballistic methods, an excess magnetising force may be required to counteract the demagnetising force due to eddy-currents caused in the laminations, and this may become considerable when the change of flux is very rapid. In order to investigate this point, an estimate was made of the demagnetising force due to eddy-currents, and this was found by calculation to be about $0{\cdot}00000046 \times dB/dt$. Now the excess H, for a flux-density of 500, required for the step-by-step method, as compared with the uniformly varying flux method, amounts to about 0·15, and this amount would be accounted for by eddy-currents if the change from $B=0$ to $B=500$ took place in about 0·0015 second, which does not seem unlikely. In the case, however, of the magnetisation curve drawn through the tops of the hysteresis loops obtained by the uniformly varying flux method another explanation must be sought, as the rate of change of flux, dB/dt, is too small to produce appreciable eddy-currents. It may be that, on slowly increasing the magnetising force from zero to a certain value and then carrying it through cycles having this value for a maximum, the value of B obtained initially may be greater than the value obtained after the iron has attained the cyclic state, owing to the first loops being unsymmetrical about the axis of H.

With regard to group (*b*), which includes methods (II.), (IV.) and (V.), it is difficult to find any rational explanation for the differences observed. The authors have, however, been impressed with the idea that when a sudden change of considerable magnitude is made in the magnetising force the instantaneous flux variation, as compared with

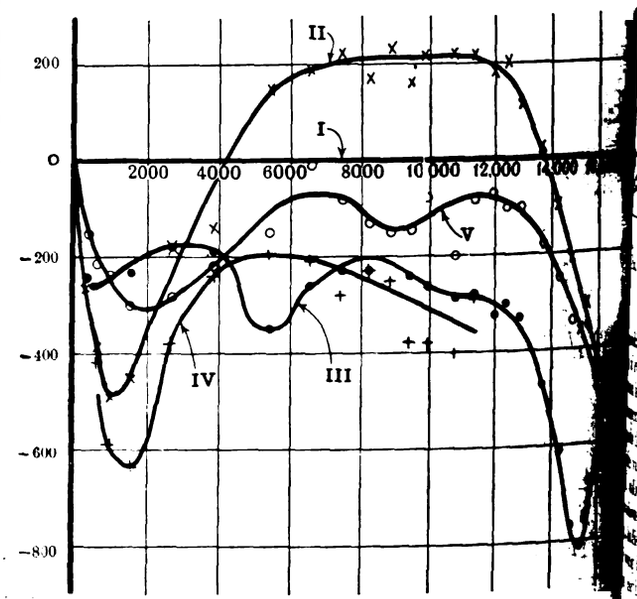

FIG. 5.—CURVE SHOWING DIFFERENCES BETWEEN MAGNETISATION CURVES OBTAINED BY VARIOUS METHODS.

the total flux variation, may depend on the steepness of the magnetisation curve at the point attained instantaneously by the flux; in other words, it might depend not so much on the permeability at that point as on the rate of change of induction with magnetising force—*i.e.*, on dB/dH. One is led to imagine that if dB/dH is great, then the stability of the molecular magnet grouping is correspondingly weak, and, keeping the Ewing model in view, one would predict that, for a sudden large change in the magnetising force, a magnetic creep depending to a certain extent on this factor dB/dH would be expected.

It will be observed from Fig. 5 that the maximum deficiency in B as obtained by methods (II.), (IV.) and (V.), occurs at about that part of the magnetisation curve where $B=2,000$, and if dB/dH is plotted it will be seen that this is where dB/dH attains its maximum value. It appears probable, therefore, that the maximum value of B attained when the iron is carried through a sufficiently large number of cycles of H depends to some extent upon the slope of the magnetisation curve at that point, B having a diminished value where the magnetisation curve is steepest.

Curves between $B=5,000$ *and* $B=15,000$.—The results appear to indicate that over this range the value of B attained for a given value of H increases as the magnetising force is carried through successive cycles, until finally a steady value of some 200 lines per square centimetre in excess of the initial value is attained.

Curves above B=15,000.—As considerable divergencies were obtained in the upper regions of the magnetisation curves by the various methods examined, it was thought that the temperature of the iron

* J. A. Ewing, "Magnetic Induction in Iron and Other Materials," p. 124.

Digitized by Google

might have some bearing on these discrepancies, for in some of the experiments the full magnetising current may have caused a rise of 100°C. in the worst case. Further investigation showed this to be the case; and the authors therefore conclude that the results obtained above B=15,000 are of little scientific value.

The degree of accuracy attainable by the various methods is next discussed, and the authors emphasise the fact that if determinations

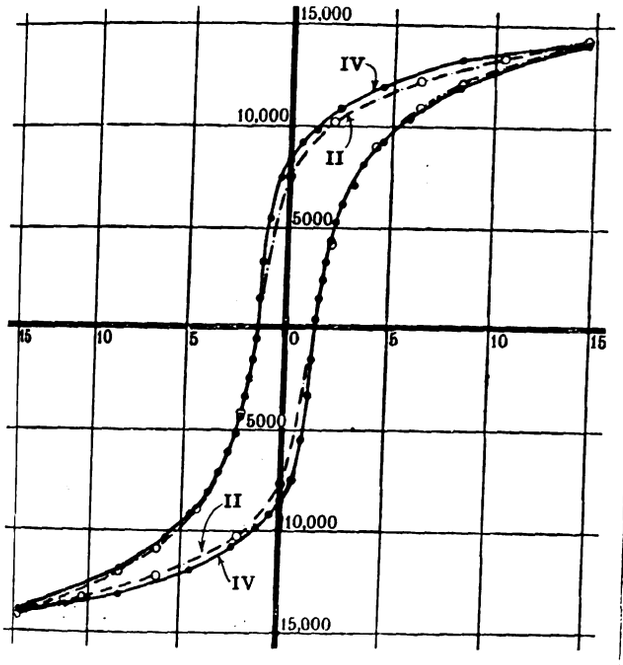

FIG. 6.—HYSTERESIS LOOPS BY METHODS II. AND IV.

of permeability upon the same sample are to be repeated with an accuracy of even 5 per cent. on the lower portions of the magnetisation curves it is essential that the ring be not subjected to considerable rises of temperature, say of 100°C., even for short periods.

As regards the time required for determinations by the various methods experimentally examined, ballistic methods are undoubtedly the most tedious, particularly when, for great accuracy, a ballistic galvanometer with a long period of swing is employed. The alternating-current method (VI.) has considerable advantages in this respect, a full set of readings of magnetising current and induced voltage occupying a very short time. When, however, it is necessary to take oscillograms at various points in order to plot curves of form factors, the time required is enormously increased. The method of uniformly-varying flux (method (I.)) is peculiarly adapted for use where time is a consideration, and at the same time a high degree of accuracy is desired. A complete magnetisation curve may be taken in a very few minutes, and the mean of many such curves obtained in, say, one hour, the iron being demagnetised between each test.

CONCLUSION.

The method of "uniformly varying flux" appears to possess advantages, both scientific and practical, over the older methods in use for the testing of ring samples of magnetic materials. It avoids difficulties due to eddy-currents and magnetic viscosity, which effects make themselves due primarily to rapid or irregular changes of flux. It also has the practical advantage that experiments may be carried out with rapidity, accuracy of repetition, and under standard or predetermined conditions of magnetic change.

The authors, therefore, would commend this method to the careful consideration of those interested in the carrying-out of magnetic tests, especially where great accuracy under definitely known conditions of experiment are essential.

THE MAKING OF WIRE LAMPS.

A VISIT TO THE "MAZDA" FACTORY OF THE BRITISH THOMSON-HOUSTON CO.

A party of visitors, made up of representatives of the daily and technical Press, was taken down to Rugby on Wednesday last week by the engineers of the British Thomson-Houston Co. The object of the excursion was the inspection of the new factory which has been erected by the Company for the production of "Mazda" lamps. These lamps have been on the market for some time past, and the factory in question has been used for their manufacture for the British market. The initial equipment was put down for the production of squirted or pressed tungsten filament lamps, and considerable ingenuity was displayed by the experts of the Company in the methods and apparatus employed in connection with this equipment. We were unofficially shown through the factory some three months ago, and were thus able to appreciate the change that has been made by the introduction of a process which it was the object of the Company to bring specially to the notice of the visitors on the present occasion.

Our readers will already be well acquainted with the general processes employed in the manufacture of pressed tungsten filament lamps; it is, therefore, of interest to turn to an innovation which has all the appearances of revolutionising the manufacture and general operation of metal lamps. The drawn tungsten filament lamp is not essentially new, because it was introduced by one of the Siemens firms some two years ago; but the B.T.-H. Co. appear to have carried the drawing-down of tungsten wire a stage further, judging by what they were able to show us in specimens of tungsten wire. It is this development in lamp manufacture to which the Company is anxious that special attention should be directed.

We understand that extensive experiments have been carried out in the United States in the laboratories of the General Electric Co., and that these experiments have resulted in the drawing-down of tungsten into extremely fine sizes of wire, even as low as 0·001 in. diameter. This wire has been found to be extremely flexible, ductile and highly durable. It is possible to handle it with ease and place it conveniently on the supporting hooks which are now commonly employed on the glass stems in metal lamps. This necessarily eliminates a number of processes in metal lamp manufacture. Pressed tungsten filament must be cut up into short loops. These have to be measured and subsequently weighed, the last-named process being the only reliable check on the resistance of each loop.

FIG. 1.—ONE OF THE DEPARTMENTS IN THE "MAZDA" WIRE LAMP FACTORY.

Each loop is then hung up on one of the hooks on the lamp stem, and the free ends welded to supports on the lower part of the stem. These are all delicate operations, and cannot be done properly unless the female workers are carefully trained.

Drawn tungsten wire, of course, renders such operations unnecessary. One end of a given length is fastened to the incoming terminal of the lamp, and the wire is then looped round on the supporting hooks and the remaining end fixed to the other terminal. The

Digitized by Google

pinching-up of these ends to the two terminals completes the operation. What it means is that the connecting of the filament to its supports in the case of the tungsten drawn wire is confined to two operations, as compared with some half-dozen in the case of the pressed filament.

Turning now to the "Mazda" lamp factory itself, the general lay-out of the building is in accordance with present-day practice. The operators are given an abundance of room, light and air. In the summer the last mentioned is cooled and in the winter it is heated. Everything is carried out on the departmental system, and the groups in the chain of processes are kept as contiguous as possible. The heavier portions of the equipment, such as the exhausting plant and the ventilating apparatus, are confined to the basement, the upper floors being devoted to space for the operators themselves. A general view of one of the departments is shown in Fig. 1.

Fig. 2.—Mazda Drawn Tungsten Filament Lamp.

The operations in the manufacture of all incandescent lamps may be subdivided into three broad heads: Those dealing with the glass portion of the lamp and the supports for the filaments; those relating to the attaching and sealing in of the filament itself; and those in which the lamp is aged, tested and capped. In the glass department of the "Mazda" factory we noticed many interesting and ingenious machines which contribute towards accuracy in result and rapidity in production The operator is depended upon to a minimum extent, and is required mainly to superintend the operation of machines. Where manual operations are concerned the "Mazda" lamp employés have been well trained and gave a striking demonstration of their deftness in the handling of extremely fine parts in bunsen flames.

As we have already stated, the actual manufacture of the tungsten wire was not shown to the visitors. They were, however, assured by the management that the work was carried on in the factory, and were conducted past the door of the department in which it was proceeding. To technical men present the principal centre of interest was a group of benches on which the Mazda wire filaments were wound on the supports. In regard to the latter, we understand that in certain types of lamp a pure molybdenum hook is used, and that in other patterns the support is formed of copper, constantan and platinum. These particular metals have been adopted, as their expansion coefficients are nearly the same as that of the filament employed. The drawn wire is supplied to the operators on small reels and is cut off in lengths which are just sufficient to go round the supporting hooks. The free end of the wire is attached to one of the terminals of the lamp before the length is cut off. After cutting, a small brass clip is attached to the loose end and acts as a weight to keep the wire from coiling up. The wire is handled just like linen thread and looped round the supports on the glass stem. The free end is then pinched on to the remaining terminal, and the length of wire is drawn taut by a slight downward pressure on this terminal. The cage is then ready for the sealing department. No other chemical process is employed in connection with the filament after this point. We understand that in the Siemens method the wire is made up of an alloy of nickel and tungsten, and after placing in position the cage is immersed in oil and subjected to a high flashing voltage which drives off the nickel, leaving only tungsten. The B.T.-H. Co. have succeeded in dispensing with this particular process, and have, therefore, simplified the operations considerably. After sealing in, the lamps are subjected to a short ageing test, in which they are slightly overrun for a number of hours. At the conclusion of this test they are photometered and passed on to the capping department. One of the new "Mazda" lamps is shown in Fig. 2.

At the luncheon which was given after the inspection of the factory it was announced that the B.T.-H. Co. were completing arrangements to supply "Mazda" wire lamps in all the present commercial sizes. For the time being they are prepared to accept orders for the 50 and 60-watt sizes for voltages from 200 to 260, and the 60-watt size for voltages up to 130, and the 10 watt for 25 volts. Until October 31st, 1911, the smaller candle-power "Mazda" lamps will be supplied with pressed filaments, after which date wire filaments will be used. Mr. H. N. Sporburg, who presided at the luncheon, stated that the efficiency of the new "Mazda" wire lamp is about 1·35 watts per British candle, and that the life of the lamp is practically the same as that of the pressed filament type. He pointed out particularly that the company attach special importance to the durability of the filament, particularly when it is first delivered, owing to the fact that it is practically a continuous length having a uniform diameter, the last-named quality being of special value. He explained that the filament becomes more brittle when used, but this is, of course, only to be expected. He thought that in placing in the hands of the public a wire lamp of high efficiency which could be roughly handled before it was put on circuit, and which would subsequently give to the electricity consumer every satisfaction during life, the B.T.-H. Co. had effected a noteworthy improvement in modern lamp manufacture. He also stated that 30,000 Mazda wire lamps were being turned out every week, representing the use of 150,000 ft. of wire.

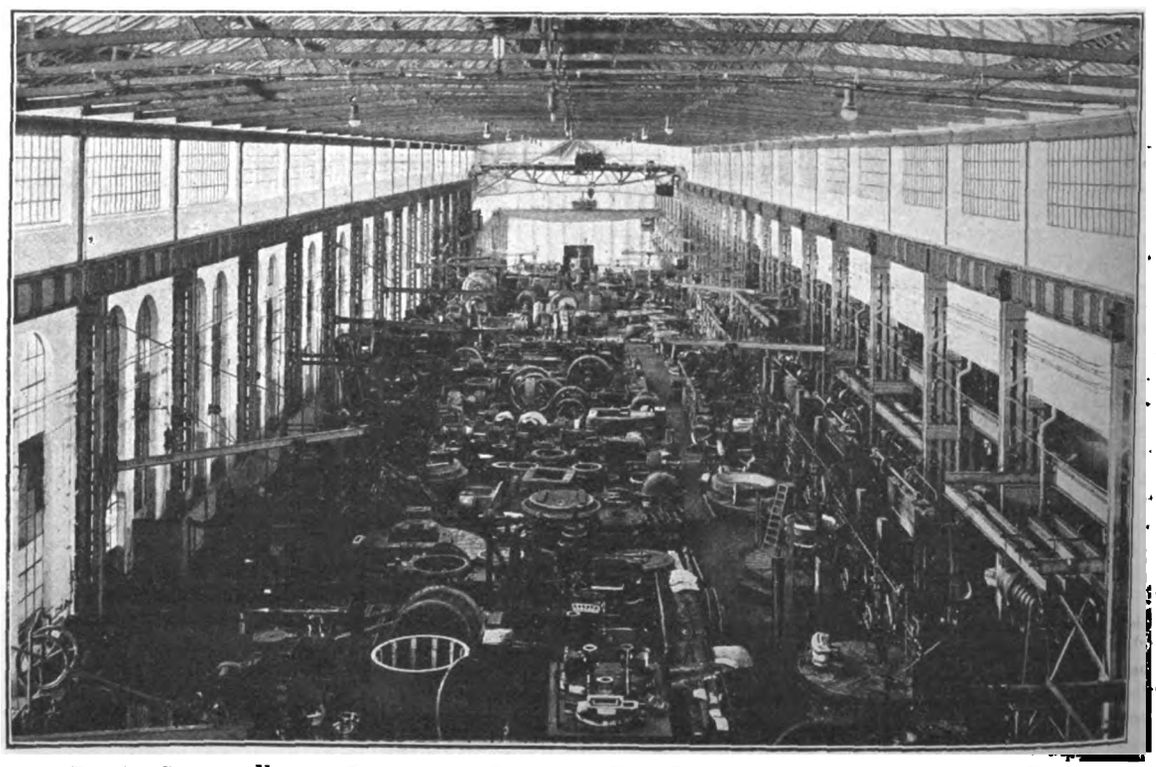

Fig. 3.—General View of Turbine and Generator Shop, British Thomson-Houston Works, Rugby.

Digitized by Google

The officials of the Company spared no pains to make the trip to Rugby interesting for the visitors, and the heavy engineering portion of the works was thrown open for inspection. Particular interest was taken in the steam turbine department, where a large number of machines of various sizes were shown in process of construction and also running on the test plate. The turbine shop (Fig. 3) is one of the most imposing portions of the B.T.-H. works, and the visitors were particularly impressed by the large amount of work which was going through. We gathered that the Company are also very busy in the other departments of the works. In conclusion, we would particularly express our thanks to Mr. Francis Willcox, Mr. I. W. Howell and Mr. F. McNeil, who conducted us through the factory and supplied us with much useful information.

EFFICIENCY IN THE ELECTROLYTIC PRODUCTION OF METALLIC CALCIUM.*

BY F. C. FRARY, H. R. BICKNELL AND C. A. TRONSON.

Most of those who have worked on the electrolytic production of calcium have been content to describe their methods and apparatus, with perhaps an analysis of a selected lump of their product, but to say nothing of the current efficiency obtained. Muthmann,† in the discussion of a Paper by Rathenau, states that by using an electrolyte consisting of two parts of calcium chloride to one part of the fluoride, and raising the iron cathode as the metal accumulated, he obtained a "good" yield. Goodwin,‡ electrolysing pure calcium chloride in a similar way, obtained a current efficiency of 21·5 to 41·9 per cent. Woehler,§ using an electrolyte containing 100 parts of the chloride to 17 parts of the fluoride, claims an efficiency of over 80 per cent. He used a current of 40 amps. at 33 to 38 volts, but does not say how often or for how long a time this efficiency could be obtained. Tucker and Whitney‖ improved the apparatus of Goodwin, and claim an efficiency of 60 per cent., using the pure chloride as electrolyte, but give no data to support their claim. As far as we are able to ascertain, no one else has published any results on the efficiency of the various processes which have been proposed.

During previous work by Frary and Badger in the Minnesota University laboratory efficiencies as high as 46 per cent. were obtained, but, unfortunately, the only runs in which the necessary data were taken were made under unfavourable conditions. As it was certain that better results could be obtained, and had been obtained, in some of the runs for which no data were at hand, these were not published at the time, and the work was continued by the present authors.

The apparatus used was the same as that described by Frary and Badger, and consisted essentially of a large crucible of Acheson graphite having a water-cooled bottom and serving as anode, and a water-cooled iron cathode a little over an inch in diameter. The crucible was enclosed in a protective layer of refractory material, and special pains were taken with the contact between it and the positive cable. The cathode could be raised or lowered at will by means of a screw mechanism.

From preliminary experiments, it was decided that the occasional feeding of the fresh electrolyte and irregular raising of the cathode were two important causes of low efficiency. Intermittent addition of electrolyte caused irregularities in the height of the melt and of its temperature, especially the latter. Too great cooling of the electrolyte caused the deposition of the metal in a spongy form, in which state it was readily lost. Spongy portions were also formed when the stick of metal extended too far below the surface of the melt, the current-density¶ being insufficient to melt the metal at the point of contact with the electrolyte, and thus produce a solid stick. This spongy metal was very likely to be dislodged and swept away by the vigorous convection currents which were always present; it also gave trouble by growing toward one side or other of the crucible, causing an increase of current at that point, with consequent increased growth of metal and a higher temperature, until finally the calcium on the edges would melt, and, being connected with the main stick only by thin pieces of metal, would be easily swept away by the electrolyte. When the end of the stick of metal was kept just below the surface of the electrolyte, the spongy metal first formed melted almost at once, and its surface tension drew it into a compact globule which was almost immediately frozen by the cooling effect of the rest of the stick and the water-cooled cathode. Thus a solid stick was easily obtained.

In starting up a run, the cold fused chloride remaining in the crucible from a previous run was heated until dry by directing the flame of a blow lamp upon it. Then a small portion of it was fused by drawing an arc from the side of the crucible with the aid of a graphite rod. A small current was used until contact was made with the cathode, when more current was put on and the graphite rod removed. As soon as good contact was assured, the direct current was shut off, and an alternating E.M.F. of about 30 volts applied. The current usually rose rapidly to about 200 amps., being regulated by raising or lowering the cathode, and the upper part of the crucible was soon filled with the molten chloride. A sufficient supply of electrolyte was added at this time to fill up the crucible, and when all was ready the alternating current was thrown off and the direct current thrown on. The current varied very little during each run, as it was taken from the 110-volt lighting circuit through a constant resistance. There was no trouble with the so-called "anode effect," except when the electrolysis was started before a sufficient amount of the electrolyte had been melted down by the alternating current.*

Since Ruff and Plato,† Muthmann‡ and Woehler§ have recommended the use of a mixture of the chloride and fluoride as the electrolyte, the authors decided to try it and see if it offered any advantages. The fluorspar was first partially purified by treatment with concentrated hydrochloric acid to remove the iron. It was mixed with the chloride in the proportion of 16·5 parts to 100, as recommended by Ruff and Plato. A new crucible was made for use with this electrolyte, having the same size as the other, but a different arrangement of the water cooling. The bottom of the crucible was turned out on the lathe so as to fit loosely over the hollow brass cooling cylinder of the Borchers‖ furnace for the electrolysis of fused salts. The crucible was then turned upside down, this space filled with a strong copper sulphate solution and copper deposited until the cylinder would not enter the space. The copper was now turned out on the lathe to fit the cylinder, and the whole of the outside of the crucible and cylinder protected from the air by a coat of Portland cement and carborundum fires and held in place, as before, by a tin former. The contact, being made through the water-cooling cylinder, was kept cool and did not burn away, as the other crucible did in the course of time. A more complete protection of the outside of the crucible was also possible.

With this crucible and the above-mentioned electrolyte, a new series of runs was made. Considerable trouble was found in making smooth solid sticks of metal with this electrolyte. The particular advantage of this mixture is supposed to be its low melting point (660 deg.). This appears to us to be a disadvantage, as the bath must be worked as a temperature of nearly 750 deg. in order to get a solid stick of metal, and the bath is so fluid at the working temperature that convection currents are more violent and more likely to sweep away the metal from the end of the stick, forming an arc. We had a great deal of trouble from this cause. Reduction of the current did not bring the desired result, as the efficiency decreased markedly.

During the runs with this electrolyte only the chloride was added, it being assumed that the fluoride would not be decomposed. However, at the close of these experiments, a sample from the top of the melt showed only 2·21 per cent. of insoluble matter, so, evidently, much of the fluoride had been lost. This loss was probably largely mechanical, and due to the violent spattering of the electrolyte.

Samples were also taken from the electrolyte in the lower part of the crucible, which had been kept frozen during the electrolysis by the cooling coil, and so, presumably, retained its original composition, and attempted to isolate the fluochloride of calcium described by Poulenc¶ and Defacqs.** but found none of it.

From the experience obtained with both electrolytes it is believed that the plain chloride is a little more satisfactory than the mixture of the chloride and fluoride in point of efficiency, and decidedly easier to manipulate. It has been shown that satisfactorily high efficiencies can be obtained with it, and that the efficiency is more largely a matter of careful regulation of conditions than anything else.

* In most cases a rod of about 1 cm. diameter was obtained, so the cathode area was about 1 to 1½ sq. cm.

* A sample of the electrolyte was taken at such a time when the "anode effect" had been more than usually troublesome, and the percentage of silica present determined. Only 0·056 of 1 per cent. was found, confirming the results obtained in the previous Paper, and indicating that current-density rather than impurities should be blamed for this "effect."

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" *commence in April and October.*

(This charge includes all the numerous Supplements.)

Vols. I to LXVI. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Jan. 31st in each year for the next following edition) 8s 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s; Europe, 2s; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents of the* 1911 *Edition sent free on application.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Reduction on quantity.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 3s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free, abroad 13s.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett. Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gelpsi and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s. [Price 10s. 6d.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. [Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton. M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE TWO-TONE VIBRATING TRANSMITTER AND CABLE INDUCTIVE SIGNALLING. By Edward Raymond-Barker. Price 1s. nett and post free. [Price 3s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E.

ELECTRIC CRANES: THEIR DESIGN, CONSTRUCTION AND APPLICATION. By H. H. Broughton. Being Vol. I. of a Complete Manual of Lifting and Hauling Machinery. *Ready in September*, price 25s. nett.

AITKEN'S MANUAL OF THE TELEPHONE. By W. Aitken, M.I.E.E. *Ready in September.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *Ready in September.*

ELECTRICAL MANUAL FOR MINING ENGINEERS. By H. J. S. Heather, M.I.E.E. *Ready in December.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

STUDIES IN LIGHT PRODUCTION. By R. A. Houston, M.A., Ph.D., D.Sc. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Hogner, by Justus Eck. *In Preparation.*

WIREMAN'S POCKET BOOK AND ELECTRICAL CONTRACTOR'S HANDBOOK. Compiled by A. W. Robinson and W. E. Warrilow. Price 5s. nett. *Ready in September-October.*

AMATEUR WIRELESS TELEGRAPH DESIGNS. By "Alfrec." Very fully illustrated. *Ready in September.* Price 1s. 6d. nett.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.: post free, 2s. 3d.

THE PROGRESS OF THE METAL FILAMENT.

From the manufacturing point of view, the progress of the metal filament has been steady and successful. It may be that some have fallen by the way, but the ranks have closed up, and the march forward has been resumed. Here and there it seems that patents have been taken out that are likely to be valuable, but the methods adopted in many cases are known only to those in the manufacturer's confidence. Still it seems likely that most of the methods resemble one another in that they consist of some plan for making a homogeneous thread out of a raw material, which consists of a powder mixed with an agglutinant. This is, therefore, somewhat different in principle from that by which the old carbon lamp was made, where the raw material most generally used was a solution of cellulose in zinc chloride. Thus, in the one case the filament is made from a more or less liquid mass, fairly homogeneous in its constitution; in the other, the filament is made from a mixture of powders with a certain amount of added fluid, which is doubtless kneaded till some approach to homogeneity is obtained. It will be remembered that this latter process is similar to that by which the Nernst lamp was produced, and though very serious difficulties were encountered, even in making the filament itself, they were largely overcome. The same thing has happened with the tungsten lamp, and everybody concerned deserves the thanks of the community for their efforts. We may hope that they are also receiving their reward in some more tangible form.

In the case of the tungsten lamp, however, the difficulties to be surmounted in the early days, say about five

Digitized by Google

years ago, were really formidable. The tungsten of commerce is very impure, and consists of a sandy powder, which seems almost as unlikely as sand itself to yield readily to any agglutinant. Further, the low resistance of the metal together with the consequent length of the filament was a further obstacle. Even so, it can hardly be said that the present filaments are as successful from the point of view of mechanical strength as we hope they will become with further years of experience.

Dr. MONASCH's article, of which we publish an abstract in the present issue, draws attention to some of the more obvious points which have been provisionally standardised; the most important are probably matters relating to the anchoring of the filament, and the general construction of the bulb in which it is enclosed. There is at any rate something approaching to uniformity in the methods adopted by different manufacturers with regard to these points. Dr. MONASCH reports the curious experience of American makers with regard to drawn tungsten wires, which have been proposed as a substitute for the powder mixtures. It seems that such wires behave with alternating current exactly in the same way as the tantalum filament; the molecular structure changes, and, for practical purposes, with alternating current, this is a very grave defect. Naturally enough, it was at first supposed that the tungsten filament, compounded of powders, would behave in the same way, but this has not been found to be the case. This is merely stated as an experimental fact; the why and wherefore is probably as mysterious as ever. We notice also that Dr. MONASCH draws attention to the results published by KINSLOE, who finds that the form of the voltage-wave affects the life and light, and that on a peaky voltage both are deleteriously affected. This result seems curious, and it is only right to say that it has not been universally accepted as conclusive. Others have stated that it is quite contrary to their opinion, and further work seems to be necessary before this can be regarded as an accepted fact.

All these things are necessarily associated with certain dislocations on the commercial side. The trading effect on the central stations is well known, though the worst is over. At the time when the Nernst lamp was in the hands of its original exploiters the general disaster that was thought to be impending from the point of view of the interests of the supply stations was admittedly in their minds, and they had plans by which they thought it might be mitigated. These troubles, however, did not then come to pass, and such palliatives as might be possible in a case where patents of a valid nature, covering more or less the whole field, were concerned, were obviously out of the question in the case of the tungsten lamp; for here nothing could be concentrated in a few hands beyond details relating to methods of manufacture, and patents could not be so broadly construed as to cover more than a part of the field. Therefore, in the present case all sorts of precautions had to go by the board, and everyone has had to do what seemed to him best, or in other words, to wait till the storm blew over. There seems little fear that the central stations will suffer any permanent harm; on the contrary, after the few lean years, there appears every prospect that a wider field is opening with a general expansion of business.

So much has been done in five years that it is reasonable to expect even greater advance in the coming years. Whether this will take the form of developments on present lines, or in further discoveries in the realm of refractory substances, it is not yet possible to say. It may be that there are other substances, lying around us, that might improve on the results tungsten has given. Probably tungsten itself was tried many a time before anything was done that looked hopeful; its low resistance and its sandy texture would lead the casual observer to think that it would be useless to devote time to its further study. If, indeed, it is to be supplanted, it is more than likely that its successor will be some other metal, now well known, but difficult to obtain in a sufficiently pure form. But even if any such metal exists, it will need more than a few casual experiments before anything definite can be known, and, in so far as making money is concerned, it would probably pay much better to devote energy to work on present lines than to hunt at random after a will-o'-the-wisp. Luckily for human progress, the inventor never believes this; and he occasionally has his reward.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Die Wechselstrom Technik. 2nd edition, edited by E. Arnold. Vol. I., "Theory of Alternating Currents," by J. L. LA COUR and O. S. BRAGSTAD. (Berlin: Julius Springer.) Pp. xiv. + 922. M 24 net.

This book is published as the first part of the well-known work of Prof. Arnold, and is intended as an introduction to the other volumes, which deal in detail with the construction and performance of transformers and machines. The present work, however, does not limit itself to the portion of the theory required for the later volumes, but goes a good deal further than is usual in an engineering treatise. The ground covered is most extensive, and one can hardly do full justice to it in the limits of a short review.

After the fundamental definitions, it begins with the theory of vectors, the representation of reactance, capacity, &c., and the operations with vectors as complex quantities in the symbolic system. The transformation of co-ordinates and the theory of inversion is given next with some applications. In Chapter IV. we find the first examples; they are well chosen, and include all points to make them representative of their kind. We are afraid, however, that two examples only are rather too few to show the practical application of the preceding theory.

In Chapters V. to X. are given the conditions affecting the working of alternating-current circuits, as well as the alterations caused by the introduction of magnetic material. Terms such as admittance, conductance and susceptance, in different combinations, are discussed and their relations stated by means of much mathematical apparatus. The theory of the transmission line is included, together with the means of keeping constant potentials at the ends. As a conclusion, there follows the construction of diagrams for a system on open circuit, on short-circuit and under normal working conditions.

These first 10 chapters, covering over 200 pages, lean very strongly on Steinmetz's "Alternating-current Phenomena," and, although the matter is treated often in a more mathematical manner, the resemblance is most striking, and it appears to us that this point should, in fairness, have been mentioned by the authors in their opening remarks.

In Chapter XI. the authors discuss the theory of the wave-form, and give mathematical and graphical methods for

Digitized by Google

splitting waves into their harmonics. A separate section is devoted to Fleming's method of determining the effective value of a wave. The Fischer-Hinnen method of calculating the harmonics, however, is not mentioned, although it is a very useful one, even if not always entirely accurate. After explaining the use of an equivalent sine wave in place of the various harmonics, the authors show the effect of the wave form on the performance of various machines, and give the results of some experimental work carried out in Prof. Arnold's Laboratory.

In the next four chapters follow the laws of polyphase currents, and extensive use is openly made of Steinmetz's methods of calculating potentials, currents and higher harmonics in such systems. At the end the authors give a scheme for a polycyclic system which they have devised for distributing over the same network current at high frequency for lighting, as well as at low frequency for power purposes. This system, however, does not seem to have yet found any practical application.

A large section is devoted to the description of instruments for measuring pressure, current, power, phase displacements, &c. Many engineers will disagree with the authors' statements that the three-voltmeter and three-ammeter methods are of no practical importance. The suggestion that properly-built wattmeters should be used instead is hardly acceptable, as in practical working it is not always possible to obtain them for an occasional measurement, and the old methods will always be a welcome help out of the difficulty. The instruments described are almost entirely of German manufacture, although the names of the British originators, such as Thomson, Cardew, Swinburne, Duddell, &c., are given.

In the next section, the iron losses and their relation to frequency, ageing, &c., are discussed, as well as the standard German tests, and a few particulars are given as to the composition of alloys used of late years in place of charcoal iron. Some information regarding stampings worked at very high frequencies, say 500 cycles, as used in wireless telegraphy generators, would here have been appreciated. This, from an engineering point of view, most important section is not nearly so thoroughly treated as the weight of the subject would have required, but as it is taken up again in the second volume in connection with transformers we assume that it was included here mainly for the sake of completeness.

The properties of dielectrics are thoroughly enquired into in Chapter XX., and methods explained by which the strain on the insulation can be reduced.

As an introduction to electrolytic cells, the authors give the theory of electrolysis with continuous current and full particulars of primary and secondary cells, which one would hardly expect in a book on alternating current. The study of the alternating arc opens with a chapter on the conductivity of gases and the resistance of air to discharges; after which follows a description of the arc between carbons, the arc in a mercury tube, the mercury rectifier and the process of electric smelting.

The last portion of the book deals with the phenomena appertaining to electric circuits and their constants. Amongst important sections should be mentioned the one referring to the increase in resistance of a solid conductor due to eddy currents, as well as that on the calculation of the magnetic forces acting between conductors of a machine subjected to a sudden rush of current. The causes of damped and free oscillations in networks are then investigated, and their natural periods calculated. The conditions of resonance in networks consisting of several parallel circuits, each containing capacity and inductance, form a very important section. The danger of switching in highly saturated transformers, when the flux cannot be established instantly, or of short-circuiting a generator when the flux cannot disappear at once, is well explained and illustrated with the well-known example of the breakdown on the Manhattan Railway in 1903.

Systems in which capacity and inductance are evenly distributed along the line are considered next, with special reference to long telegraph cables. Power transmission with continuous current and an overhead line is also investigated. The closing chapter discusses the theory of surges along different networks and suggests means of damping them down. After describing and criticising the various arrangements of arresters proposed to protect machines and apparatus, the authors touch upon the question of how far a surge penetrates the winding of a machine.

From this short *résumé* it will be apparent that the book covers most thoroughly the whole ground of alternating-current theory; if anything should be criticised, it should be the fact that the authors, in their anxiety to give a very complete account of every question, have included a large amount of matter which is not essential to the subject, and thus reduces the perspicuity. As examples of this, we would mention the primary and secondary cells in Chapter XXI., the electric discharges in gases in Chapter XXII., the theory of commutation in Chapter XXIV., and the continuous-current transmission line in Chapter XXV. We are also afraid that the book will prove rather inaccessible to a large number of engineers and students on account of the difficulties offered by its mathematics and abstract representations of systems, as well as because of the paucity of the examples. A comparison with Steinmetz's, Thompson's, Ferraris' or Karapetoff's works comes quite naturally to one's mind, where practical examples are worked out at the end of every chapter to make the reader familiar with the magnitude of the quantities under consideration.

To some extent this volume outbalances the whole work, as it makes one feel that, in addition to the construction of machines, there should be practical parts to follow, dealing with the design and lay-out of distributing networks, construction of switchgear and switchboards, protecting apparatus, &c.

The references to other works given in the book are very incomplete and not in accordance with the accuracy of the authors in every other direction. A short list of publications could easily be given at the end of each chapter if continuous references through the text are found undesirable. The book must have cost an enormous amount of work to compile, especially as the previous edition had to be re-written entirely. The first edition of 1903 contained also the theory of the transformer, which has now been transferred to Vol. II., and its place is now taken by the theory of transient phenomena. All plates, diagrams, &c., are entirely new, the lettering adopted being in accordance with the recommendations of the International Committee.

In conclusion, we should like to say that, despite the minor faults mentioned, full credit should be given to the authors for the high value of their work, which will be a welcome addition to the reference library of any engineer, and that its usefulness would be still further increased if in a future edition all secondary matters and unnecessary mathematical complications were omitted. R. ORSETTICH.

Elementary Principles of Alternating-Current Dynamo Design. By A. G. ELLIS. (London: Blackie & Son.) Pp. vi.+305. 12s. net.

The most exasperating kind of book to a reviewer is one that absolutely refuses to excite his wrath or to arouse his enthusiasm. It is surely an indifferent kind of book where every bit of praise can only be bestowed grudgingly and all condemnation must be mollified.

This is the position, however, we feel Mr. Ellis has placed us in. To praise his book for its excellence would be exaggeration, but it would be equally unjust to condemn it for its worthlessness.

Of course, no one will deny the author his right to treat design in his own way, but for our part there is but one test for any book on *this* subject, namely, its practical utility. From this point of view there are only two ways in which such a book can be profitably written. Firstly, as a text-book for the student or teacher; secondly, as a handbook for the engineer. For the former, the present book is far too general and unmethodical; for the latter, there is too little evidence of the author's familiarity with modern design and practical data to be authoritative.

Digitized by Google

Had such a book appeared some years ago, it might possibly have met with more appreciation, but with the stringent methods of training recently developed both here and abroad, along with the immense amount of accurate information in all branches of engineering which is now available, we cannot class the present book as first-rate. The method followed by Mr. Ellis is largely that used by his former chief, Mr. Hobart; but we think he would have been better advised to work on the more scientific lines adopted in the leading treatises on design and electrical engineering.

The reason therefore that we do not heartily recommend the book to the student or engineer wishing to study design is because he can get his wants supplied better elsewhere. Although there are a number of details where we might join issue with the author, especially on his design, particulars and methods of calculation, yet it is the treatment as a whole that "leaves us cold."

AUTOMATIC TELEPHONE SYSTEM AT CHICAGO.*

BY C. M. BRADFORD.

Summary.—A description is given of the automatic apparatus used in Chicago on the system operated by the Illinois Tunnel Co.

The independent telephone system operated by the Illinois Tunnel Co. in Chicago comprises eight exchanges, equipped with automatic switchboards. The district which is covered by the system at present extends for over 8 miles, embracing the stock yards and a large portion of the residential district on the south side of the town, the business district of the Loop and vicinity and reaches well into the residential district on the north side. There are eight exchanges.

The trunking system is based on the usual scheme of having all the numbers in each exchange commence with a figure which is used only in that exchange or its branches. For example, all the numbers in the Chronicle building exchange commence with the figure "3" and run from 31,000 to 36,500. The North exchange is a subsidiary to the Chronicle exchange, and its numbers run from 37,000 to 38,500. Connector switches—third selectors and line switches—are installed at the North exchange, but no first selectors or second selectors; consequently anyone calling the North exchange from the Brooks building, for example, operates a first selector switch in the Brooks building exchange, which selects an idle trunk to the Chronicle exchange; he there operates a second selector switch, which picks out an idle trunk to the North exchange. A third selector is there operated and extends the connection to a connector switch at North, which completes the connection to the person desired.

Provision is made for handling calls to the long-distance switchboards in the usual way, by having the words "long distance" printed on each dial number disc at the back of the "0" finger hole, so that in the near future, when the long-distance board is in operation, any subscriber will be able to secure a recording operator by turning his dial once from this finger hole. Information clerks can be rung up from all exchanges by calling the number 392, and the complaint clerks by calling the number 393.

The information and complaint clerk's desk is installed at the Chronicle building headquarters, and all calls of these kinds are received there from the entire system. The board has four positions, so designed that a call causes lamps to glow in all four positions, and the first idle operator answers it. The first five information trunks are represented in the first position by white lights, in the second by red and in the third and fourth by green lights. Five other information trunks end in white lights in the third position, red lights in the fourth position and in green lights in the two other positions. The trouble trunks end in white lights in the second and fourth positions, and in red and green lights in the other positions. Each operator answers white lights first, red lights next and then if idle answers green lights. In this way distribution of the load is secured without eliminating co-operation. This arrangement gives a very rapid and satisfactory service. The board is now handling about 2,400 calls per day, most of which are enquiries for the numbers of new subscribers.

Subscribers' complaints are distributed from the complaint desk to the record clerks' desks located at the various exchanges by means of telautographs. These ingenious devices enable the complaint clerk to send by wire an autograph copy of each complaint to the record clerk at the exchange in which the complaint should be investigated. This clerk acknowledges receipt of the complaint by a signal. With this system no complaints are lost—all are transmitted quickly and receive prompt attention.

A "wire chief's" desk is installed at each of the exchanges, except at two of the auxiliary exchanges. At these latter testing outfits are installed, but arrangements are made so that lines at these exchanges may be tested also from their respective main exchanges. Following the practice adopted in most of the later automatic systems, the "wire chief" does not test the lines by means of the old-fashioned shoe or test-jack plugged in at the cross connecting frame, but by means of test connector switches, one of which is mounted on each line switch unit. By using these switches the wire chief can test any line, either in or out, without the aid of a rack man or other assistants. This makes the testing of the lines considerably more rapid and economical than by the old method and saves a great deal of wear and tear on the protectors of the cross connecting frame.

When the long-distance board is installed these special switches will be used by the long-distance operators in setting up connections. This will make it possible to supply more current on each long-distance connection than is supplied on a local connection. It will also be possible for a long-distance operator to call an automatic telephone line and hold it while waiting for the completion of a long-distance connection without automatically ringing the local telephone bell.

The remaining exchange equipment comprises the automatic switchboards and power plants, which are of the standard type of the Automatic Electric Co., and very similar to those installed at San Francisco, Spokane, Calgary, Havana, and in other later systems. Some details about this equipment may, however, be interesting.

Each exchange is equipped with apparatus for individual lines—four-party lines and private branch exchange trunks. Line switch units of the usual type are employed, which carry 100 line switches with two master switches on one side and banks for 15 connector switches, with 10 regular connectors and one test connector mounted on the other side. The master switches on the line switch side are not linked together, but each operates its group of 50 lines independently. Seven trunks are installed from one group of 50 line switches and eight from the other to secondary line switches. Primary line switches are arranged in sections of 2,000 each, each section being served by 100 first selector switches. Consequently, the 300 trunks from the 2,000 primary line switches pass through 300 secondary line switches arranged in 10 groups of 30 each; then through 100 trunks to 100 first selector switches. Local connections are then trunked through second and third selectors in the usual way. Connections outgoing from any exchange to other exchanges are trunked from first selector switches through another group of secondary line switches for the purpose of making trunks between exchanges as efficient as possible. This practice is the same as that used in San Francisco. Each such trunk also passes through a repeater, so that a calling party receives talking current from the battery at his own exchange. Talking current is, of course, supplied to each called party from the connector switch employed at his exchange. The four-party line line-switch units carry 21 connector banks with 20 regular connectors arranged in four groups of five each, and one test connector. The rotary connection or private branch exchange line-switch units carry 21 connector banks, also with 15 regular connectors and one test connector. These switches make it possible to give a private branch exchange subscriber any number of trunks, all of which appear under one number in the directory, for by means of them a calling party is automatically switched to an idle trunk.

The power plants at the various exchanges consist of pink Tennessee marble switch panels, equipped with the full complement of knife switches, circuit-breakers, ammeters, voltmeters, &c. Each exchange is served by one large storage battery. In order to make it practical to charge the battery and to use it at the same time without materially raising the voltage on the bus bars to the automatic switchboard, counter E.M.F. cells are installed in each battery room. These are connected to a counter E.M.F. cell switch mounted on the power panel, so that the cells may be cut in and out one at a time on the leads from the battery to the switchboard. Further to aid in keeping the voltage on the switchboards properly regulated, a Weston voltage alarm relay is installed in connection with each switchboard, so that if the voltage drops below or rises above predetermined points an alarm bell will immediately be rung. Duplicate motor generators for charging and duplicate machines for ringing individual lines are provided, as well as duplicate harmonic converter outfits for ringing on party lines. These are mounted on marble panels and are installed at each exchange as a part of the power switching board.

The subscribers' instruments are of the latest type, equipped with a two-wire calling device and direct-current receivers. A party-line telephone is the same as an individual line, except that the ordinary

*Abstract of an article in the "Telephone Engineer."

Digitized by Google

individual line ringer is displaced by a harmonic ringer. Private branch exchanges of three different types are in operation in connection with the Chicago system—namely, intercommunicating systems of the push-button type, systems using small manually-operated switchboards the same as those commonly used in connection with manual central exchange systems, and full automatic switchboards.

As has already been mentioned in connection with the rotary connectors, spoken of in the description of the exchange equipment, each of the private branch exchange systems of the first two types may have several incoming trunks and an incoming call is switched to an idle trunk by means of the rotary connector switches at the exchange. An idle outgoing trunk is selected by the calling subscriber using a push-button intercommunicating system. Each trunk is represented in each push button box by a key, so that a subscriber wishing to make a call presses a key corresponding to one trunk, and if he then receives the busy signal he tries another trunk.

An idle outgoing trunk from a switchboard employing an operator is, of course, selected by the operator in the usual way. She then proceeds to secure the party desired by switching her calling device on to the idle trunk and operating it in the usual way; or, if the subscriber has a telephone equipped with a calling device and desires to call the number himself, or to make a number of calls in succession, without bothering the operator, she connects him through to a non-busy trunk and he calls whoever he wishes. The trunks may be two-way, or separate trunks may be used for incoming and outgoing business as desired. These boards are so designed that each operator has double lamp supervision over all calls through her board. The equipment operates on 24 volts, using current furnished from the large storage battery at each central office. The battery supply leads are bridged with dry cells and condensers.

The Chicago telephone public has been very favourably impressed with the service given by the new company. It was, of course, expected that patrons would be pleased with the elimination of the operator and with the speed of the service given by the new system, but the Tunnel Company's officials have been considerably surprised by the large number of compliments they have received on the excellence of the transmission through the new system. The amount of calling through the various offices is rapidly increasing and becoming quite heavy as the list of subscribers grows and the public learn more and more to use the new telephone. The service is especially popular among the brokers on La Salle-street, where quick numerous connections are desired during Stock Exchange hours. A supervisor in the Brooks building exchange who happened to be watching calls made by one of these brokers a few days ago timed a few of his connections with a stop watch, and found that in 65 seconds by the watch the broker called four different parties in succession, talked to each, and disconnected.

THE MAGNETIC PROPERTIES OF NICKEL STEEL.*

BY DRS. E. COLVER-GLAUERT AND S. HILPERT.

Summary.—The authors give an account of a number of tests they have made on various alloys of nickel-steel. The magnetic investigations were carried out with a Du Bois magnetic precision balance, the material being heated in an electric furnace, while alcohol or petrol ether cooled with liquid air was used for the lower temperatures.

For a considerable time a certain school of thought, following the views published by Osmond, has considered that the various magnetic phenomena exhibited by iron and its alloys are solely due to allotropic modifications of the metal, and that α-iron, which is supposed to be stable below 730°C. when in a pure state, is magnetic, whilst the β and γ varieties are non-magnetic. The latter are said to be only stable above 730°C. and 890°C. respectively when in a pure state, but may be preserved at lower temperatures either by rapid quenching or by the addition of foreign elements, when a material which is non-magnetic at normal temperatures results. A certain amount of difficulty was encountered, since it was alleged that martensitic and austenitic steels consisted of either β or γ-iron, and many of these steels are strongly magnetic. The explanation given for this fact was that the quenching or other means of preservation had been inadequate to retain the whole of the iron in the β (or γ) condition, and that there was thus a certain quantity of iron which had changed into the α condition intermixed with the other varieties. This, however, does not appear to be very plausible, since in such a case, owing to the finely divided and distributed nature of the magnetic substance, the magnetisability of the whole could only be very low, whereas the exact opposite is the case.

This difficulty appeared to have been surmounted when Maurer* was able to produce a practically non-magnetic steel, consisting of pure austenite, by the rapid quenching of an alloy containing about 2 per cent. of carbon and 2 per cent. of manganese. Against this evidence it may be stated that such an alloy must be regarded as a special case, as the conditions are so complicated that it is impossible to draw any conclusions from such a product and to assume that they are also correct for pure iron. The authors' present series of steels also provide much evidence against the so-called austenite being a non-magnetic material.

One of the authors has recently studied this question,† with regard to pure iron, and proved conclusively from purely magnetic data that β-iron cannot exist. It was further possible to prove that even if γ-iron is non-magnetic when in equilibrium, there is no proof that it need be so when under-cooled, and there is no magnetic distinction between α and γ-iron.

Quenching the 5 per cent. nickel steel from 600°C. causes, as might be expected, only a very small difference in properties as compared with the same steel when slowly cooled. In both cases the microstructure shows the material to consist of ferrite and pearlite. When the steel is quenched from 900°C. a marked change occurs. The coercive force is more than double that of the previous ones, the maximum induction is considerably lower, and the curve has the appearance that is associated with a hard steel. The micro-structure shows the whole mass to be of a medium coarse martensitic nature. Contrary to this, however, quenching from 1,240°C. produces a softer material with a coercive force considerably below that of the specimen quenched from 900°C., whilst the maximum induction closely approximates to that of the slowly cooled alloy. This quenching temperature is far above that of the critical points of carbon steels, and is most certainly within the γ-range of temperature, in spite of which the magnetic properties are almost identical with those of a steel which has had every possible opportunity of assuming the α condition. The micrographic examination reveals two constituents, one of which assumes a much darker colour than the other. The lighter coloured one appears to have a pitted surface, and in places there are patches of a very coarse martensitic nature.

The changes which occur during the thermal treatment of the alloy containing 25 per cent. of nickel are of a much more complicated nature. It may be regarded as representative of the irreversible nickel steels, since at this point the temperature-hysteresis of the series reaches its maximum. As delivered from the works, this steel is non-magnetic, and quenching from 600°C. (in the γ-range according to Osmond) does not affect this property. If the quenching temperature is raised to 900°C. the material becomes slightly magnetic, whilst if it is still further increased to 1,240°C. the alloy becomes strongly so; in fact, it possesses a permeability approximately equal to one-fifteenth that of pure iron. The authors regarded the non-magnetic condition as the stable one for this alloy, and were therefore greatly surprised on finding that the slowly cooled specimen was even more strongly magnetic than the one quenched from 900°C. It was thought that probably some cause for this would be revealed if the steels were cooled to such a point as where they re-assume strongly magnetic properties. This point is quoted differently by various investigators. Hopkinson places it at —52°C., but both Osmond and Dumas assume it to be slightly above zero. The authors' steels were cooled to zero several times but no change in the magnetic properties could be detected. The further cooling was undertaken in three stages, and conclusively proved that there is no sharply defined temperature at which the steels become completely magnetic, as is shown in the theoretical diagrams published by Guertler and Benedicks, in addition to the previously mentioned investigators, who constructed their diagrams from the practical results of experiment, but that the change begins probably at some temperature a little above —50°C. and gradually proceeds as the temperature falls, being more or less complete at —180°C. A most remarkable fact is that when the latter temperature is reached the alloys are in the same relative positions as regards their induction curves as they were before any cooling took place, and that the slowly cooled alloy and the one quenched from 1,240°C. are more magnetic than the others by practically the same number of units as they were in the original state, despite the fact that, at intermediate stages, the properties have varied very considerably. The only explanation of this fact seems to be that by quenching from a high temperature or slowly cooling a certain amount of a strongly magnetic material is produced which persists through all subsequent treatment. If this were mixed with a fairly large proportion of the non-magnetic substance (which occurs nearly pure in the alloy when quenched from 600°C. or 900°C.) it would account for the fact that, though *per se* the substance is strongly magnetic, the mixture only appears partly so. The unmagnetic sub-

* Abstract of a Paper read before the Iron and Steel Institute.

* "Zeitschrift für Electro-Chemie," 1909. † "Metallurgie," 1910.

Digitized by Google

stance, of course, becomes magnetic when cooled to low temperatures, and thus permits the permeability of the previously magnetic one to be more accurately estimated. If the originally magnetic substance were only magnetic to the degree shown by its induction curve, it is improbable that after cooling to −180°C. it would retain its original advance over the rest of the material; but if it originally possessed the permeability shown by the curve after the cooling, it would appear that this treatment has rendered the non-magnetic substance a better conductor, thus enabling the true value of the original material to be measured, whilst previously this was impossible owing to the finely divided state of the substance. The micrographic examination of these alloys does not afford any explanation of their magnetic properties.

To provide a theoretical explanation of these results is also a matter of great difficulty, being very much complicated by the behaviour of the alloy when slowly cooled, but the authors hope to obtain more information on the subject by a further set of experiments, which will consist in re-heating the alloys to various temperatures for a considerable time, and by noting the magnetic changes to form a clearer idea of the exact conditions under which the alloy assumes the unmagnetic state. As a tentative explanation of the facts, it appears as if a strongly magnetic substance were formed at high temperatures, which is not indicated in the equilibrium diagram, and that this disassociates at some point between 600°C. and 900°C., but tends to re-form below the former temperature, under favourable conditions (very slow cooling). This opinion will probably have to be modified very considerably when more data is obtained, but in the light of present knowledge it seems to be the only possible explanation in accordance with the facts.

The 33 per cent. nickel alloy is only very slightly affected by the drastic thermal treatment to which it was subjected, and it seems possible that there may be some connection between its remarkably low coefficient of expansion, and the very small change in its magnetic properties. The coercive force in every case is exceptionally small, and the material seems to be extremely soft (magnetically). There is a slight increase in the hardness as the temperature of quenching rises, the maximum induction showing a very small reduction, the coercive force an increase, and the general shape of the curve is that of a harder material, though as regards the latter property, the specimen quenched from 600°C. seems to be as hard as any of the series. The steels are unchanged by cooling below zero. The metallographic examination also shows only comparatively little change.

The following conclusions are drawn from these experiments: 1. A 5 per cent. nickel steel is hardest (magnetically) when quenched in the neighbourhood of 900°C. Quenching from higher temperatures results in a softer material. 2. The changes which occur during the thermal treatment of a 25 per cent. nickel-iron alloy are of a far more complicated nature than has previously been thought. At high temperatures there probably exists a product which may be preserved by rapid quenching, and is then strongly magnetic, and persists to the temperature of liquid air. This product does not exist in the region between about 600°C. and 900°C., but for another which is also magnetic can possibly occur at about 300°C. There is very little connection between the magnetic properties and metallographic structure. There is no sharp magnetic change point for this alloy below zero, but the permeability gradually increases as the temperature decreases from about −50°C. to −180°C. 3. The magnetic properties of a 33 per cent. nickel-iron alloy are only very slightly affected by thermal treatment. Despite the "γ-iron structure" produced on this steel by the more general etching media, it is strongly magnetic and soft. 4. There is no connection between magnetic properties and micro-structure. 5. There is no evidence that if γ-iron exists it is non-magnetic. 6. The microstructures of commercial nickel steels are practically the same as those of meteoric iron.

NOTES ON DESIGN, CONSTRUCTION AND OPERATION OF HIGH TENSION ELECTRIC TRANSMISSION LINES.*

BY C. D. GRAY.

The author discusses some of the points that should be considered in designing, constructing and operating aerial high-tension transmission lines, voltages above 10,000 being considered as high tension.

The distance to which power can be transmitted economically depends on the cost of fuel and labour, the railroad facilities of the district and the first cost of the complete power development. The present limit seems to be from 200 to 250 miles on the Pacific coast. The longest one in the east is that from Niagara Falls to Syracuse, about 160 miles. These limits are being extended by the introduction of higher voltage apparatus, so that to-day 150,000 volts is not considered beyond the bounds of reason, 110,000 being now used on four or five systems.

The possibility of building steam plants at the coal-fields where culm or other cheap grades of fuel could be used, for transmitting power to neighbouring cities has been proposed. There is one company doing this at the present time in Pennsylvania, the Harwood Power Co., which distributes power at 30,000 volts.

Voltage and Size of Wires.—Coming now to the transmission line, the voltage and number of circuits are usually the first points to be decided. These depend more particularly on the amount of power to be transmitted and the allowable loss and the distance, but the character of the load in respect to power factor, load factor, desirability for securing continuous service and character of country over which the line is to run, are also points to be considered. In general the voltage is determined from the allowable losses in the line with the most economical size of conductor. Kelvin's rule applies fairly well to this determination. A so-called "rule-of-thumb" method is that the pressure in kilovolts shall be equal to the distance in miles. In any case this problem usually resolves itself into a "cut-and-try" method for the first attempts in determining the size of the conductor, which can be carefully calculated later. A starting-point for conductor size is usually No. 4 copper or No. 2 aluminium for the smallest size to be used on short spans, and No. 2 copper and No. 0 aluminium for longer spans on account of mechanical strength. This being the starting-point, the voltage may then be determined to keep the loss within the limits desired. By loss is meant the actual C^2R, or ohmic loss (and not the voltage drop). This is usually kept from 5 to 10 per cent. of the delivered power. When duplicate circuits are installed, it is satisfactory to allow this loss when both are in service. If one is out for a time the generating voltage can be raised sufficiently to keep the delivered voltage at its proper value.

The number of circuits to be installed depends on the amount of power to be transmitted and the continuity of service required. In general, if it is necessary to keep the initial cost of the development low, and the system to be supplied has another plant or a steam plant kept under steam with engines or turbines floating on the system, it may be the best engineering to instal but one circuit. In many cases, where the voltage allows, the poles or towers may be equipped for two circuits and but one installed at first until the demand for power increases sufficiently to warrant the cost of installing the second circuit, or the loss becomes too great on one circuit.

In regard to the advisability of installing two circuits on one line of poles or towers, this is entirely feasible up to 35,000 volts on wood poles. With steel towers, duplicate circuits of any reasonable voltage can be employed. This type of construction is cheaper than the installation of each circuit on its own poles or towers, but has the slight disadvantage that some causes of interruption will put both circuits out of service simultaneously, such as falling trees or large branches that will touch both circuits at the same time. Greater care must also be used in repair work on account of the proximity of the live circuit. There is no advantage in single lines in respect to the usual causes of interruption, such as lightning, surges, mechanical breaks in wires, insulators, pins, poles or towers, caused by wind or ice strains on conductors and such as short circuits or earths caused by conductors swinging together or into the supporting structures.

Another problem that arises is to determine the connection of the circuits, whether delta or star, and if star, whether to earth the neutral at the power-house and sub-stations or not. Engineers differ in regard to this question. For voltages up to 45,000, it is probably better to operate delta in most cases, and above that value to connect star with the neutral earthed, although some systems at higher pressures are operated delta, the Central Colorado Power Co. being an example.

The delta-connected circuit can be operated on two wires, and if single-phase transformers are used one of a bank of three can be taken out without appreciably disturbing the voltage relations, the only effect being that it reduces the capacity of the bank. The voltage between any wire and earth is greater with the delta system for a given voltage between wires than for the star-connected system.

The star circuit can be operated on two wires, provided there is a "dead earth" at both ends of the line, but the voltage on the phases is apt to be somewhat unbalanced, depending on the conditions of the earth, their number and distance apart. Two transformers can also be used with the same disadvantage. The earthed neutral star-connected system lends itself better to the use of the Nicholson and other similar methods of testing for broken insulators or earth on the system.

The size of conductor is dependent not only on the losses but also on the sleet and wind conditions, especially for steel-tower construction. The allowance to be made for these factors depends on the section of country traversed by the line and the factor of safety de-

* Abstract of a paper read before the Brooklyn Engineers' Club.

Digitized by Google

sired. It is generally safe to use 8 lb. wind pressure on the projected area of the wire, together with ½ in. radial thickness of sleet in sections where sleet forms. This wind pressure is equivalent to an actual velocity of about 56 miles per hour or an indicated velocity of 70 miles per hour.

The amount of sleet to be considered is a much-debated question, especially with aluminium wire. Some engineers say that sleet will not form on a live conductor and not at all on aluminium. The writer believes that it will form on aluminium, especially after the wire has been installed for some time so that the initial greasy coating has had time to wear off and the oxide has formed on the surface. While sleet is not apt to collect on a live wire with high voltage, still there is always danger of the wire becoming dead, due to some interruption, and then the sleet does form.

From a reconnaissance of the district it may be decided whether it would be best to use poles or towers. If there is any question in this respect, the approximate cost of right-of-way, clearing, hauling material, digging holes, &c., must be found, also whether or not the locality is subject to wind, sleet or lightning storms of especial severity. All of these factors must be considered before deciding upon a definite route.

Right-of-way.—The problem of securing reasonable prices for rights-of-way is much more difficult for a high-tension line than for a railroad, as there are no attendant advantages to the land owners unless they are broad-minded enough to realise that the general community will be benefited by cheap power which will benefit them indirectly. Such persons are, however, usually scarce. The right-of-way may be purchased in fee-simple, in which case it may be fenced or not, depending upon circumstances. Usually the farmers are allowed to cultivate the land provided they do not injure or interfere with the line in any way. This is advisable as it keeps down grass and brush which might cause trouble from fires or require cutting periodically. The right to enter the right-of-way strip either by patrolmen or repair waggons should be reserved. It is best to have nothing stated in the deeds regarding cultivation, but to allow it, so that in case the power company desires, it may fence off its property.

Often easements are obtained for setting poles or towers. These may be perpetual or limited by time, preferably the former. In this case the right to enter the property, patrol the line and repair it must be secured. If possible the centre line should be defined across each property without the number and location of poles or other structures specified, as it often happens that additional ones may be desired later, which gives the owner an opportunity for cancelling the original contract and demanding exorbitant prices under the new agreement.

The width of right-of-way to be secured depends on the number of pole lines and the cost of land, but should not be less than 100 ft. for any important line and should be entirely cleared of trees and brush, and if the section is subject to forest fires, fire trenches should be ploughed along its edges to help protect the structures from damage and prevent fires from crossing the right-of-way if possible. All trees outside this right-of-way strip that would reach the line in falling should also be cut. All timber and brush should be disposed of in some way or burned so that dead branches will not be picked up by the wind and blown across the circuits or furnish fuel for forest fires. If easements are secured the clearing should be done in the same manner. In rough country it may be necessary to make waggon roads or paths so that the construction, patrolling and repairs may be done more easily. After the right-of-way options have been secured for the entire line, with more or less flexibility as to route, a survey party should be put into the field and the centre line of the right-of-way located.

Construction Features.—The type of construction to be adopted depends on the importance of the system, number of circuits needed, first cost of construction and the cost of maintenance and repairs. The cheapest in regard to first cost for a single circuit is of course a wood-pole line, the poles being spaced as far apart as possible consistent with safety. This depends on the size of conductor and the wind and sleet conditions to be encountered. In the writer's opinion 200 ft. is the maximum span allowable and from 125 ft. to 150 ft. is better for average conditions with moderate-sized conductors. This refers to a single three-phase circuit with an earth wire for lightning protection.

The stresses in the wire and poles should allow for a factor of safety of at least two under maximum wind, temperature and sleet conditions.

The kinds of timber principally used in wood-pole construction are chestnut, cedar, cypress or juniper, red wood and pine, the latter being used principally when impregnated or treated with some wood preservative. All of these woods will rot more or less at the ground line and may be protected to prevent this action. As the price of poles goes up, due to the scarcity of timber, it becomes more necessary to prolong their life or make use of concrete or steel construction.

The methods of treating are (1) impregnating the entire pole by the vacuum process, using creosote, zinc chloride or other wood preservative; (2) the open-tank method of boiling the butt in one of the same preservatives for 7 or 8 ft., and (3) the brush treatment of the entire butt or only the section around the ground line extending 2 ft. below and 1 ft. above the ground. In the writer's opinion the treatment of the entire pole is not justified, and possibly the open-tank method may also be too expensive at the present time. It is then a question of using the brush treatment, which may increase the life from 25 to 50 per cent.

Wood Poles v. *Steel Towers.*—Among the advantages claimed for wood construction are cheapness in first cost, ease of construction, the insulation of the pole between the conductor and the ground (which is of doubtful value on high potentials), and the possibility of having a cross-arm or pole top burn off from an arc caused by a defective insulator without interrupting the service. A single line of poles of this kind may in some instances be installed at the side of highways, electric or steam railways where permitted, thus saving the cost of right-of-way and rendering patrolling easy.

Some engineers and operating men prefer two wood-pole lines each carrying a single circuit, to a double-circuit wood-line, even though the first cost and maintenance are much greater, believing that two circuits on separate structures even on the same right-of-way are not so liable to interruption from a common cause, and also that repairs can be made on one safely while the other is alive. Some prefer two wooden-pole lines to a double-circuit steel-tower line for the same reasons, even with the greater cost of the pole lines and the much greater cost of maintenance.

It has always seemed to the writer, however, that the steel construction is the better on account of the fewer insulators per mile and the lower cost of construction and maintenance. The life of the best wood construction is not over 12 to 15 years, while steel towers should be good for an almost indefinite period, provided they are properly maintained.

No data is available regarding the life of steel towers, as they have not been used long enough to determine their life, especially if galvanised. Galvanising should be good for 10 or 12 years, and then, by painting every two or three years with some good preservative paint, such towers ought to last 40 to 50 years or even longer.

Single-circuit pole construction does not lend itself well for supporting an earthed arrester wire over the power conductors, as some sort of an iron support must be used. On a double-circuit wood-pole line this wire can be carried on the top of the pole, preferably installed on a pole-top pin and insulator, the insulator merely being used to furnish a smooth support for the wire and to which it can be tied. Among the other disadvantages of wooden construction are the increasing cost of poles in all sections of the country, the decreasing factor of safety of the line with the age of the poles and the difficulty of transporting poles in mountainous regions.

For wood construction the cross-arms should be of extra size. Iron pins with separable thimbles for cementing into the insulators should be used, and in general the construction should be the best in all respects.

Concrete poles are coming into use, replacing wood, but they have been of such recent construction that no conclusion can be made regarding their durability. They will doubtless be used more and more as wood increases in price and more data is available regarding their characteristics. The practical disadvantages of concrete poles are their high first cost in manufacturing, hauling and erection, and the difficulty of obtaining uniform product. There is also the problem of fastening the cross-arms to the poles so that the fastening will be substantial and not corrode.

Wood and concrete poles lend themselves best to the use of pin-type insulators which may be used with reasonable safety up to 66,000 volts, beyond which voltage suspension-type insulators must be used. The latter require greater lengths of supporting cross-arms on account of the tendency of the insulators to swing as pendulums about their supports, which increases the strain on the cross-arm and the torsional effect on the pole.

We will not consider tubular or small built-up latticed steel poles, the cost of which is too high to consider for high-tension line work. In some cases where the lines are run along railroad rights-of-way such as the New York Central, New Haven or Long Island railroads, where the voltage is restricted to from 11,000 to 22,000 volts, they may be used, but their cost is very high.

Steel-tower, long-span line construction is the best in nearly all cases where private right-of-way or easements can be secured, if it is possible to use high voltage so that the conductor is kept within a reasonable size. These towers should be made up of small structural shapes such as angles and channels. Some engineers and manufacturers of towers make use of rods, flats and pipes, but it is best to use only angles and channels bolted together in the field. Certain mem-

Digitized by Google

bers, however, such as cross-arms for holding the insulator supports and the earthed wire support, may be made of two channels latticed together and riveted in the shop so that the whole member can be galvanised. The other members should be galvanised after the holes are punched, galvanised or sherardised bolts being used in all cases.

In designing towers of this kind it should be borne in mind that they cannot be designed by ordinary structural or bridge formulæ, as the factor of safety and deflection of the different members are so different. A factor of two or three is used and deflections that would not be safe in other types of construction, so that the design is more or less the result of experience and of tests on sample towers built up and actually tested with the different loads and combinations of loads that may be imposed in actual service. In making such tests, if the material for the test tower has not been galvanised, an allowance should be made, as the strength may be decreased from 15 to 20 per cent. by galvanising.

Towers should be designed for the standard height and strength desired and then extensions of 10, 20 or 30 ft. should be designed to fasten to the bottom of the standard towers to make higher ones. These extensions should be arranged to bolt to the corner legs of the towers without any drilling or fitting in the field. All towers should be designed to take the same wire stress as the standard towers, in fact the stress in the wires and the clearance to ground should be kept constant and the sag and span varied. In this type of construction it is interesting to note that the cost of line per mile is practically the same for different heights of towers and lengths of span with the same size conductor and stress on it. This statement, of course, applies within certain limits and could not be used in all cases.

Double-circuit towers of the ordinary construction support six power conductors, one earth wire and two telephone wires. The towers should withstand torsional stresses due to one circuit being broken on one side of the tower, or both circuits being broken on the same side, that is each tower should be a dead-end tower.

The spacing and location of wires differ for different voltages, but a safe rule to follow is that on long spans nothing less than 60 in. be used up to 60,000 volts, and this increased 1 in. for each 1,000 volts over 60,000. With suspension-type insulators care should also be taken to see that when the insulators swing with the wind they do not come too near the supporting structure. It is usual to assume them swinging to an angle of 45 deg. from the vertical, and in this position the wire should not be nearer the supports than 20 in. for 60,000 volts, plus $\frac{1}{2}$ in. for each 1,000 volts over 60,000. It often happens that light wires, especially aluminium, will swing beyond 45 deg. In fact, the writer has seen wires blown out nearly horizontal, in which case the clearance mentioned above should be maintained with the horizontal position of the wire. Power wire should be at least 22 or 23 ft. above the ground at the lowest part of the span and the telephone wires might be 6 ft. lower. This minimum clearance depends on local conditions.

The anchors for the towers are always separate from the corner members and arranged to bolt to them, so that they can be set before the towers are erected. The best form of anchor consists of an angle about 6 ft. long with a cross consisting of two pieces of the same material about 2 ft. long bolted to it. This type will usually develop enough holding-down power to satisfy the requirements in all kinds of ordinary soil.

Field Construction.—The cross arms, earth wire supports and insulator pins are usually put on before the poles are raised and the insulators installed later just previous to the stringing of the wire, to prevent breakage and loss by theft or otherwise. Often times for voltages of 35,000 or less, the insulators are installed when the poles are on the ground.

The wires are usually strung by hand or with a team. If the ground is rough or aluminium wire is used, which is easily abraded by dragging on the ground, it is run through snatch blocks attached to the poles or towers so that it does not touch the ground.

In the construction of the line, the holes are usually dug by one gang and the anchors set and tamped in by another. The towers are assembled complete on the ground by one gang and erected by another gang, the erection usually being done by the use of a gin-pole or derrick. All the wires are usually installed at the same time and the telephone wires connected up for use with portable telephone sets, so that the construction gangs can keep in touch with each other and the construction office.

The methods of fastening the wires to pin-type insulators consist of different ties or mechanical clamps. For ties, the double or so-called Mershon tie is good, especially for aluminium wire where it is necessary to protect the wire for some distance beyond the insulator head against arcs from the upper petticoat. This tie consists of two ties, one on each side of the insulator. One end of the tie wire is started at the head of the insulator and served around the main conductor outward for 3 or 4 in., the wire is then carried around the tie-wire groove of the insulator and the end again served outward from the other serving until the main conductor is covered for 3 or 4 in. beyond the edge of the upper petticoat of the insulator. Another similar tie is used on the other side of the insulator. It is usual to protect the conductor in the wire groove of the insulator with a sleeve of the same material as the conductor. This sleeve extends just beyond the head of the insulator. It is usually of U section with the ends swaged out, so that it will not cut the conductor, and when it is installed it is hammered down on the top so that it will be held in place.

Mechanical clamps are also used, but, in the writer's opinion, are not so good as the above tie as they tend to cut and abrade the conductor and do not protect it from arcs. The above protecting sleeve and method of tie is especially desirable when aluminium wire is used, which is more easily abraded and affected by arcs than copper. For use with suspension insulators, various types of mechanical clamps are used, designed so as not to injure the wire.

The problem of obtaining satisfactory methods of splicing the conductors on long-span work is a difficult one, as the strength of the conductor is limited by the strength of the joint. The joints that seem best adapted to this work are the twist-sleeve joints made longer than usual so that three or more complete twists of the conductor can be made.

The author finally discusses the proper operation of the line and also gives a few details of costs of construction. These show a slight increase in cost of a single-circuit steel-tower line over a wood-pole line. Also a saving in cost of a double-circuit steel-tower line over two single-circuit wood-pole lines or steel-tower lines. In the writer's opinion, the double-circuit steel-tower line is the one to instal in most cases where two circuits are needed, unless the system is a very important one and the initial expense of two lines on separate routes is justified in order to secure continuous service.

MR. ROSLING'S ADDRESS TO THE VICTORIAN INSTITUTE OF ELECTRICAL ENGINEERS.*

On the first page of our rules you will find the objects of this institution, viz.: (1) The exchange of ideas and information on electrical science and kindred subjects, by the reading and discussion of Papers. (2) The furtherance of the interests of electrical engineering by concerted action. (3) The cultivation of friendly relations between the members of the various branches of electrical engineering and its allied industries.

We have carried out the first and third items with some success and pleasure, but we have not done very much in furthering the interests of electrical engineering by "concerted action."

I propose to bring to your attention some opinions that I have heard expressed upon certain conditions at present prevailing, which press hardly upon electrical engineers in Australia generally and on the industry in Melbourne particularly. I refer more especially to the combination of professional with contracting work, a practice condemned alike by clients, consultants and contractors in other civilised countries, and to the unlimited powers in favour of the purchaser inserted in the "general terms and conditions" usually issued with specifications calling for public tenders.

Electrical engineering is itself a comparatively young industry, but has made phenomenal growth, and here, in Australia, a young country as far as civilisation is concerned, the growth has been perhaps more rapid than in the older countries. In all phases of life, certain practices, which in youth are quite mete and proper, must be put aside as beneath the dignity of maturer years; so with electrical engineering. In a young country with a scattered population, in the early stages of development, it is hardly to be avoided that contractors should do almost the whole of the advising and consulting work, but, as the industry grows, it becomes more and more advisable to separate the consulting from the contracting work. Further, the qualities required for excelling in either branch are diametrically opposed; a good consulting engineer should be entirely impartial in formulating the scheme which he considers will be most economical and satisfactory in use, and in choosing the plant which he considers will give the best results, whereas a good contracting engineer should be a firm believer in the particular plant he has to sell, and should use his best endeavours, if his plant does not suit a scheme, to make the scheme suit his plant.

When a contracting engineer considers the question of preparing a scheme for public tender, there are three courses open to him. Firstly, he can prepare the specification to the best of his ability, and

* Abstract of the Presidential Address delivered by Mr. P. Rosling.

Digitized by Google

stand aside altogether as a contractor, but adjudicate on the merits of the respective tenders. This is perhaps the least objectionable method, but it may prevent him recommending the use of certain plant which he, as a contractor or a supplier, is interested in, and which he believes to be the best of its kind, and he may have to accept a tender from a firm for plant which he has previously considered of an inferior nature. Moreover, he is almost certain to find that he does not receive full and proper tenders from certain firms who are naturally shy of putting the whole of their information before a probable future competitor.

Secondly, he can prepare the specification or specifications for the work, send in a tender to his own specification, and leave it to some other engineer to adjudicate on the tenders and supervise the carrying out of the work. One objection to this method is that besides divided responsibility, it is highly improbable that the adjudicator will see eye to eye with the author of the specification, and the scheme as carried out will differ in detail from the original design, usually causing the client extra expense, or a loss to the contractor, who has to work to one man's specification as interpreted by another. The greatest objection, however, to this method is that, whether he does or not, the contractor preparing the specification is credited by his competitors with ear-marking certain details of the plant or method of installing the same, in order to give himself an advantage in tendering, thus giving rise to a spirit of uncharitableness.

On the third course, where the contractor prepares the specification, tenders himself, and adjudicates on the different tenders, and finally supervises the carrying out of the contract, it is hardly necessary to comment.

There seems to be the probability of several large schemes of electrical power installation coming to a head in the immediate future, and these, together with country town lighting and extensions to present plant, should provide scope for one or two engineering firms carrying on consulting work only; and if we, as an institute, possibly in connection with our friends in New South Wales, follow the example of the English and American institutes, and set our faces against the practice of contracting engineers preparing schemes for public tenders, the public would very soon see that it was to their advantage to follow our lead.

While on the subject of consulting engineers, it is to be hoped that here in Australia we may begin where the leading consulting electrical engineers in England and America have already arrived, namely, that the consultant in his specification will state what is to be accomplished, and broadly how it is to be done, and give such details as the power that is to be installed and the overload and efficiency required, leaving the manufacturers and the contractors to state how they will give the desired results with their standard apparatus.

With regard to conditions of tendering, it is the favourite practice in Australia to specify that, in case of disagreement, the decision of the buyer or his engineer for the time being is to be final and binding on both parties, that is, the contractor is to have no redress whatever over some quite legitimate misunderstanding. Such terms are sufficiently onerous when a contractor is dealing with an engineer whom he has found to be fair and reasonable, but with general terms and conditions, put in the words "the engineers or officers for the time being," in what sort of position is a contractor should anything happen to the engineer during the completion of the contract, and a stranger, with quite different ideas, supervises the completion of the contract. He probably does not see eye to eye with his predecessor, and the unfortunate contractor, having agreed to the general terms and conditions, may be in a very precarious position.

At present, I understand, some firms refuse to quote to such terms, and others put in a percentage to cover contingencies, even, I believe, in some cases insuring the life of the engineer for the time the contract is likely to last, for an amount they may consider they may lose through the change of engineers during the course of the contract, but as contingencies of this nature are pure guesswork, it brings an element of gambling into the contract which is quite out of place.

All this uncertainty and trouble could be done away with by inserting a proper arbitration clause. Contracting engineers do not mind how stringent terms and conditions may be so long as they feel that in the event of serious disagreement they can refer the matter to an entirely independent authority; and I cannot see how any competent broad-minded engineer can object to an arbitration clause.

Such alterations to present conditions cannot be brought about all at once, but if members of this institute, and our friends in New South Wales, would agree to recommend that no member should act in the dual capacity of contractor and consultant for a scheme for which public tenders are to be called, and, further, that any member, when preparing specifications for public tenders, should insert a proper arbitration clause in the general terms and conditions, I think that before long the present unprofessional and uncommercial conditions would cease to exist.

Another matter which we, as a local body, ought to take in hand is the education of the Electricity Committee of the Melbourne Town Council on the question of rates for power and heating. It has been shown conclusively in the daily Press how much more economical electric lighting is than gas; but for heating and power we are in competition with coal as well as with gas, and although, starting on the same basis, the present rates show many advantages in favour of electricity, the margin of cost is often not sufficiently wide to induce people to discard their present plant and substitute electric heaters, cooking apparatus and motors.

In developing a load for an electricity station, you are met with the problem that costs can be reduced only by increasing the output of the plant installed, and usually that the output can only be increased by reducing the prices. There are two methods of meeting this problem: one is to be content to go very slowly and allow the load to increase through the numerous advantages electricity has over its rivals almost irrespective of cost, and very gradually reduce prices as the increased load reduces cost; the other is to make up your mind what your output is likely to be at a certain date, with prices per unit that that output will justify, and offer your current at the price, irrespective of a possible present loss, and leave no stone unturned to ensure that your estimate of output will be found to be under rather than over the mark.

As an example, the author refers to one of the power companies in England. It is not necessary, however, to go outside Australia for an example of the benefit of cheap power rates. Sydney has now a flat rate of 1½d. per unit and a sliding scale rate of 4s. per month per horse-power capacity installed, plus ¾d. per unit used. With the flat rate of 1½d. per unit (the sliding scale rate has only just come into force), Sydney's output for power and heating is more than double that of Melbourne, where the charge is 2d. per unit on the flat rate, or 2½d. per unit for the first 75 hours' full load use per month, and ½d. per unit thereafter, a sliding scale which, on the average, does not prove of much use.

Working from the present averages, and the result of Sydney practice, if the Melbourne Council made the power rate 2d. per unit for the first 45 hours' full load use per month and ¾d. thereafter, it would greatly encourage the use of motors, and would bring cooking and heating electrically into prominence, as it would bring the price to the average householder to about 1d. per unit for these purposes. For large users the price should be reduced still further, depending upon the hours worked, even down to ½d. per unit for a 24-hours' load, or for a limited hour supply.

Ethically, I believe, it is open to argument whether a municipal council should endeavour to run its various departments to show a profit for the relief of the rates, or should so adjust prices as to leave each commercial department just paying its way after allowing proper depreciation and sinking funds. Commercially, however, situated as we, the ratepayers, are in Melbourne, it is extraordinarily short-sighted to turn over electricity profits to the relief of rates, instead of reducing prices to consumers.

In a modern city like Melbourne, with its mild winters and hot summers, there should be neither coal nor gas used outside the electricity generating station. Electricity is the ideal means of supplying power, heat and light, and it only rests with the Electricity Committee to embark upon a bold and vigorous policy in order to make the electricity supply scheme a most valuable asset to the ratepayers, at the same time making Melbourne one of the best electrified cities in the world.

Another reason which is probably helping Sydney to go ahead faster than Melbourne in electrical matters is that they are not there handicapped by the single-phase system, for, although this is perhaps the best and simplest system for transmitting current over large areas for lighting purposes only, it is hopelessly behind a two-phase or three-phase system directly power begins to assume a noticeable portion of the load.

Melbourne used to be considered the leading business and manufacturing town in Australia, but, as far as the use of electricity is concerned, it is content to take second place to Sydney. Not a little blame for this state of things must be put to the debit of the Melbourne City Council for the way they have neglected the interests of the ratepayers in failing to give them the advantages of a cheap power supply, and some little blame must be attached to the electrical engineers in Victoria for not being more energetic in inducing people outside the industry to take more interest in the way the industry is throttled.

The foregoing address was prepared before I had the pleasure of reading Mr. Forbes Mackay's most interesting address to the Electrical Association of New South Wales, and I find that, to a certain extent, we are in phase with one another. One paragraph I take the liberty of quoting verbatim:—

"It rests with us to see that the public has constantly kept before it the fact that electricity is the form of energy best suited for use for

Digitized by Google

all purposes—in the office, in the home and in the factory. I consider it nothing short of a crime against humanity to instal any but the most wholesome, convenient and economical public services in new towns and cities. But if those who should do not insist, and insist in the most public way, on the mistake which will be made if old-fashioned, unwholesome, inconvenient and uneconomical services are installed, they will continue to be installed. The average man, whether he thinks it of himself or not, is conservative. In mechanics, we are taught that a body which has been put in motion tends to move in a straight line. It requires the application of force to cause a change in the direction of motion of a body. A man in his life resembles the moving body, inasmuch as if he be not pushed or pulled in one direction or another, he tends to do to-morrow what he is doing to-day, and to go on doing it as long as he lives. Each of us must push or pull as many members of the public as we are able to influence in the direction of discarding old-fashioned methods of lighting, heating, cooking and driving machinery in favour of what I am convinced is the only perfectly satisfactory method."

THE ACCIDENT AT MILLBROOK ON THE STALYBRIDGE, HYDE, MOSSLEY AND DUKINFIELD ELECTRIC TRAMWAYS.

The report of Lieut.-Col. P. G. von Donop, R.E. regarding the accident which occurred at Millbrook on the Stalybridge, Hyde, Mossley and Dukinfield Tramways on June 5th last has now been issued by the Board of Trade.

It will be remembered that the driver of a car descending this hill lost control and that the car on reaching the curve at the bottom overturned. Thirteen passengers, of whom one subsequently died, were seriously injured and 20 others were slightly injured. The car was of the four-wheel, single-truck type and was fitted with hand and magnetic track brakes. There are compulsory stops at the top, bottom and halfway down the hill and speed is limited to four miles an hour. The steepest gradient is 1 in 11·4. The approach to the top of the hill is on a right-handed curve and at the top there is a left-handed curve. The rails appear to have been in a slippery condition.

The driver had already taken the car once down the hill on the morning of the accident and both then and on other previous occasions the same day the magnetic brake had acted satisfactorily. According to his evidence, before the accident the driver brought his car to the top of the hill, and stopped. Then he started and gradually moved his controller handle over the braking notches till he reached the fourth and last without effect. Then he shut off the magnetic brake altogether and tried to stop the car with the hand brake. In connection with this evidence the inspector points out that the driver acted entirely contrary to instructions. According to the rule for coasting gradients he should have set the controller handle at the fourth braking notch, and eased off his brake; on the gradient on which the car was standing no application of power was necessary to start the car, as it would have at once commenced to run forward by its own weight, and the magnetic brake would then have come into action whilst it was travelling at a low rate of speed; if this speed was found to be too low, the controller handle might then have been moved to the third notch, which would have allowed a slightly increased speed to the car before the brake came into action again. The special object of this rule is to ensure that in coasting down a hill the brake is applied whilst the car is running at a very low rate of speed, but the driver's action in first applying power and then applying the magnetic brake at the second notch would have prevented the brake from coming into action until the car had attained a comparatively high rate of speed. It may also be pointed out at the same time that the driver admitted that he had entirely neglected to carry out the instruction to test his magnetic brake before starting down the steep gradient.

According to the conductor's evidence the car was stopped at the top of the hill, but of the 10 passengers whose evidence was available, seven were positive the car did not stop, one first said it did not stop and then stated it did, while two were not certain whether it stopped or not. The driver and conductor on a car which had just ascended the hill and was standing at the top both stated that they were watching the car to which the accident occurred and that it did not stop. Further, they stated that the driver was applying his hand brake very hard and that shortly after running past the compulsory stopping place they saw him apply the magnetic brake. Neither witness could, however, state whether the hand brake was released before the magnetic brake was applied.

From the above evidence the inspector concludes that the car failed to stop at the top of the hill and that it ran past the compulsory stopping place at a high rate of speed. At the inquest the driver of the car admitted that he did not stop the car.

The inspector concludes that there are no grounds for attributing the runaway to any defect either in the hand or in the magnetic brakes. He has no hesitation therefore in deciding that this runaway must be attributed in the first instance to want of care on the part of the driver, in allowing his car to approach the top of the hill at a considerably higher speed than that allowed by his regulations; and, secondly, to the driver's want of skill in the manipulation of his brakes when he lost control of the car.

The Westinghouse Brake Co. are now fitting their magnetic brake equipment with an additional contrivance, which enables the track brake to be applied mechanically as well as magnetically; the driver has thus the power to apply the track brake, even though the wheels of the car are not revolving. For gradients such as those which exist at Stalybridge, this device would form an additional safeguard, and the Joint Board might be asked, the inspector thinks, to consider the advisability of fitting it on their cars.

As regards the overturning of the car the curve was examined after the accident and it was found that at one point its curvature was 56 ft. The superelevation was also examined and was found to be very irregular. The maximum was 2¼ in., but at some points, even where the curvature was sharp it was as little as ⅛ in. Under these circumstances it was almost inevitable, Col. von Donop considers, at the speed at which the car was travelling that it should be overturned.

This is now the third case, the inspector points out, which has occurred on this hill of a car having been allowed to get out of the control of the driver, and there is clearly no assurance that it will not occur again. To a runaway car, the curve at the bottom of this hill is an almost certain source of danger, and it is imperative that some steps should be taken to minimise the danger arising from it. The want of uniform superelevation could be corrected by banking up the road, and this should in any case be done forthwith. But the curve itself requires relaying so as to do away with the very sharp portions of it which now exist. It should, in fact, be so relaid that the curvature should at no point be sharper than the 1½ chains radius originally approved for it. This is a more difficult matter, as it will probably entail some widening or diversion of the road. But until this alteration to the curve is carried out, Col. von Donop does not consider that any top-deck car should be allowed to travel on this hill. The improvement on this curve is a matter calling for the Joint Board's urgent attention.

TRAMWAY AWARD UNDER CONCILIATION ACT.

In connection with the recent dispute between the Leeds Tramways Committee and their tramway employes, as the Committee failed to effect a settlement with representatives of the men's organisation (the Amalgamated Society of Tramway and Vehicle Workers), Mr. Askwith, K.C., of the Board of Trade proceeded to Leeds on August 3 to act as conciliator between the parties. Mr. Askwith, who was accompanied by Mr. D. C. Cummings of the Board of Trade, met representatives of the parties, and subsequently presided at a joint meeting, at which an agreement was arrived at.

For purposes of comparison with the terms of employment on the tramways of other powers we set out the agreement which was made on Aug. 4, 1911, between the Corporation of Leeds and the Amalgamated Association of Tramway and Vehicle Workers (Leeds Branch):—

1. That the working hours of conductors and motormen shall be as nearly as possible an average of 54 hours per week of six days.

2. That the following scale of wages be paid to conductors and motormen upon the understanding that payments for bonus, meal reliefs, and long spreads be discontinued, except as hereinafter stated.

Conductors.	Hour.		Week.
For first six months of satisfactory service .	5¼d.	...	24s. 9d.
For next twelve months	5⅝d.	...	25s. 10½d.
For next twelve months	6d.	...	27s. 0d.
Thereafter, if not appointed as motormen ...	6¼d.	...	29s. 3d.

Motormen.	Hour.		Week.
For the first six months	7d.	...	31s. 6d.
For the next twelve months	7¼d.	...	32s. 7½d.
Thereafter	7½d.	...	33s. 9d.

On all duties when the spread-over does not exceed 12 hours a margin of three hours be agreed to with no deduction for meal time; on all duties exceeding a 12-hour spread, and up to 15 hours, a margin of two hours be allowed. On all duties exceeding a 15-hour spread a margin of one hour be allowed. When a duty exceeds 12 hours a half-hour shall be deducted for meal time.

3. That upon the expiration of seven years' satisfactory service by

Digitized by Google

conductors or motormen a merit stripe and 1s. a week extra wages be allowed as at present.

4. That spare conductors and motormen be guaranteed five and a half days' work per week of six days.

5. That where a conductor who is qualified as a motorman is so employed he shall be paid at motorman rates, and such time shall aggregate towards his next advance in wages.

6. That all time worked by motormen and conductors over 58 hours per week of six days be paid at the rate of time and a quarter.

7. That the wages of car cleaners (night staff) shall be 6d. for the first twelve months, 6½d. for the next three years, and 6¼d. after four years' service, previous service to count.

8. That the wages of labourers to car repairers and motor-overhaulers, as in clause 9, sandmen and greasers be for the first six months 22s. per week, for the second six months 23s. 6d. per week, after further twelve months 25s. per week, thereafter 26s. 6d. per week.

9. That the scale of wages for car repairers (night staff) and overhaulers (day staff) be as follows:—

	Per Week.
On appointment and for first six months	27s.
For next twelve months	28s.
For next twelve months	30s.
Thereafter	31s. 6d.

10. That the scale of wages for controller and trolley attendants (night staff) be as follows:—

	Per Week.
On appointment at age of 18	15s.
Second year, at age of 19	17s.
Third year, at age of 20	19s.
Fourth year, at age of 21	21s.
Fifth year, at age of 22	23s.
Sixth year, at age of 23	24s.

11. That overtime at the rate of time and a quarter for the first two hours and time and a half afterwards be paid to the shed staff engaged on night duty.

12. The Corporation guarantee that the percentage of spread-overs shall not increase in future, but, so far as possible, shall be decreased.

13. This agreement shall be subject to six months' notice on either side, but no notice shall be given before Feb. 4, 1914.

The London County Council tramway employés, who are agitating for an increase of wages, have formulated their demands as under:—

1. Minimum wage for adult labourers to be 30s. per week.

2. Rates of pay to be 5s. per day on entering the service and for the first four months, 5s. 6d. per day for the second four months, 6s. per day after eight months, and 6s. 6d. per day after 12 months.

3. Hours of labour to be eight per day—48 per week.

4. Rates of pay for all public holidays to be time and a half, with the exception of Christmas Day, which shall be paid at the rate of double time, or in lieu thereof three days' holiday per man per annum.

5. All men called upon to work upon their recognised weekly rest day to be paid at the rate of time and a quarter.

6. All overtime—that is to say, all time worked over schedule time (as per time-board)—to be paid for at the rate of time and a quarter.

7. All men promoted to positions as inspectors, &c., whilst on probation to be paid at the rate of 7s. per day, the period of probation not to exceed one month.

8. Court of appeal to be established to deal with cases of dismissal from the services of the Council.

The Aberdeen Tramways Committee is considering a request by the motormen and conductors for an increase of wages.

Motormen and conductors for ordinary week-day duty demand 5d. an hour on appointment, 6d. on completion of one year's service, 6½d. on completion of two years' service and 7d. on completion of three years' service. Members of the staff with more than two and three years' service to be granted an immediate increase in accordance with these rates. The rate of pay for Sunday work (motormen, conductors, cleaners and repairers) is to be increased from 8d. to 9d. per hour; and payment for work on week days over and above regular duty must be made at rate of time and quarter.

PARLIAMENTARY INTELLIGENCE.

GOVERNMENT CONTRACTORS AND FAIR WAGES.

In the House of Commons on Friday Mr. LANSBURY asked the Postmaster-General whether the Peel-Conner Telephone Works (Ltd.) were carrying out work for his department at a new telephone exchange in London; if so, whether they were employing telephone wiremen at 7d. per hour, although the rate for men of that trade was 9½d. per hour.

Mr. H. SAMUEL said he had made inquiries into the case, and his information was that the rate of 9½d. per hour to which the hon. member referred did not apply to telephone wiremen, and that no infringement of the fair-wages clause had taken place in the case of the Peel-Conner Co.

Mr. BOWERMAN asked if it was customary to recognise as fair a firm which on every other class of work pays unfair wages.

Mr. H. SAMUEL said no. The President of the Board of Trade a year or two ago said that if a firm was notoriously a bad employer it would not be retained on the list of Government contractors, even though the wages paid on Government contracts were strictly in accordance with the fair-wages clause. But he had no information that the particular firm was in that class.

Mr. POINTER inquired if the department could adopt the same attitude as corporations, and insist on trade-union wages for the whole of the employés.

Mr. H. SAMUEL said the attitude of the Government was declared on the occasion of the debate. He did not think they should be justified if they had a very small contract with some large firm in investigating all the conditions of employment throughout that firm's factories and insisting on trade-union rates being paid for all work.

GLASGOW TELEPHONE OPERATORS.

In the House of Commons last week Mr. MACCALLUM SCOTT asked the Postmaster-General whether, while National Telephone Co. operators with five years' company service, on being taken over by the Post Office, would be entitled to the full period of annual leave in 1912, the ex-Corporation (Glasgow) operators, who had already completed five years' Post Office service apart from previous company and Corporation service, would not receive the full period of leave until 1913.

Mr. H. SAMUEL said that, although in some respects the staff of Glasgow Corporation telephone department would have been less favourably treated than the staff of the National Telephone Co. on transfer to the Post Office, the conditions of transfer, taken as a whole, were more favourable to the former than to the latter.

Mr. MACCALLUM SCOTT asked the Postmaster-General why the transfer conditions comprised in the memorandum of 1905, relative to the staff of the National Telephone Co. were not applied to the staff of the Glasgow Corporation telephone department on its transfer to the Post Office, in view of the fact that the memorandum was issued previous to the transfer of the Corporation undertaking; and whether he was aware that it produced discontent in the public service that such discrimination should be made on the transfer of different staffs engaged on exactly similar work.

Mr. SAMUEL said the memorandum was drafted to give effect to the recommendations of the Select Committee of the House which sat in 1905 to consider the provisions of the agreement of Feb. 2, 1905, between the Postmaster-General and the National Telephone Co. The case of the Glasgow Corporation staff did not come within the purview of the Select Committee's report or of the memorandum. The Glasgow Corporation staff had benefited by comparison with the National Telephone Co. staff in that after a comparatively short period of employment under the Corporation they were taken into the service of the State more than five years earlier.

ELECTRICITY SUPPLY WORKS AND STRIKES.

In the House of Commons on Monday, Mr. LANSBURY asked the Home Secretary by whose authority soldiers were sent to occupy the Poplar electricity works last week, how long they stayed and at whose request and for what reason they were removed.

In reply, Mr. CHURCHILL said he did not know to which of the electrical stations in Popular the hon. member referred, but he might say that before troops were brought to London a list was prepared by the police and military authorities of the places to be specially guarded, because of the serious injury to the public which would ensue if damage were done by rioters. The chief electrical stations were on the list, and pickets were sent to them accordingly. He could not speak as to the actual circumstances that occurred inside any particular station. But the rule undoubtedly which they had usually followed had been that soldiers should be sent in aid of the civil power when thay had been advised by the local authority. In the present situation the military authorities had been charged with general duties for protecting the property of the railways and for securing law and order in the maintenance of traffic. For the purpose of discharging that duty it had been necessary to employ a large number of troops, and those troops had been placed under the orders of different generals who were responsible for certain areas in the country. Those officers in the discharge of their duties had been given and would continue to enjoy full discretionary power to move troops along the lines of railway to such points as might enable them to safeguard as far as possible the ordinary working of all necessary traffic.

New Acts of Parliament.—On Aug. 18 Royal Assent was given to the following Acts:—

Telephone Transfer, Expiring Laws Continuance, Dunfermline & District Tramways Order Confirmation, Edinburgh Suburban Electric Tramways, Paisley District Tramways Order Confirmation, Electric Lighting Orders Confirmation (Nos. 1 to 5), Tramways Orders Confirmation, Paignton U.D. Council, South Lancashire Tramways, London, Brighton & S. Coast Railway, Northampton Corporation, Winchester Corporation (Electric Supply), Sidmouth Gas & Electricity, Liverpool Overhead Railway, Metropolitan Railway, Bristol Tramways, Central London Railway, Nottinghamshire and Derbyshire Tramways, Middlesbrough, Stockton and Thornaby Tramways, Metropolitan Electric Tramways, London, Tilbury & Southend Railway, Rhondda U. D. Council, L.C.C. (Tramways and Improvements), Aberdare U. D. Council, Brighton, Hove and District Rail-less Traction, East Kent Electric Power, Halifax Corporation, Rotherham Corporation, Newcastle Corporation and Corporation of London (Bridges).

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Abercarn.—The Council have adopted a scheme for the construction of electric tramways in the Western Valleys.

Arnside (Lancs.)—Public electric lighting is about to be introduced. Current will be supplied by Mr. Thos. Wilkinson, who has put down generating plant at his residence.

Burnham.—The Council have asked Mr. W. H. Trentham to report upon the proposal to erect electricity works in the district.

Cotton Mill Driving.—Albert Mill, Accrington, is running several looms by electric power supplied by the Corporation. It is stated that so far as the running is concerned the new power is all that could be desired, but it works out about 1½d. per loom more than the old method.

Customs Duties.—It has been decided that, under the Australian Commonwealth import tariff, the duty on electric bells, automatic arc lamp couplings, lampholders, ceiling roses, rosettes, wall plugs and Morse telegraph instruments is 17½ per cent. ad val. (10 per cent. for British goods). Rosettes and wall plugs suitable only for telephones can be imported free. The duty on shade galleries for electric lamps is 25 per cent. (British 15 per cent.) and on "Meggers" 5 per cent. (British free).

It has been decided that under the French import tariff the dynamo of small ventilating apparatus "consisting of a dynamo with metal wings" is liable to duty as a "dynamo-electric machine" and the wings of such apparatus are subject to duty as "detached parts of machines (other than electric)," or "manufactures of nickel, other" or "nickelled manufactures"—according to kind. Large ventilating apparatus, without electric equipment to be worked (by transmission band) by an electric motor is included under 512bis as "Ventilators, according to size," and large ventilating apparatus provided with coils and electrical attachments under 524bis, "electrical apparatus, according to kind." In the case of electric cranes, the motor, rheostat, crane and wagon or truck are subject to duty separately (under 524, 524bis, 525bis and 614, respectively.)

Carwen.—An inquiry was held here on Aug. 22 into the application of the Corporation for permission to borrow £7,600 for extensions of the electricity supply undertaking. It was reported that the demand for energy for power and lighting was increasing, and it was necessary to put down additional plant to meet the demand.

Fire.—A fire broke out at the Gillingham electricity supply stores on 15th inst., causing damage estimated at about £2,000. The supply of electric current for public and private lighting was not interfered with.

Glasgow.—At the meeting of the Corporation yesterday (Thursday) the Tramway Committee reported on the recent strike of the Corporation tramway employés.

At a meeting of the Committee on 14th inst. it was resolved to leave the settlement of the dispute in the hands of the General Manager, although an attempt was made to refer the subject matter of the dispute to an arbitrator of the Board of Trade, whose decision should be binding on the parties for three years.

Holmfirth.—The Council have adjourned for six months the question of obtaining electricity supply powers, but a plebiscite of the ratepayers will probably be taken on the subject. It is suggested that the Council should take current in bulk from the Yorkshire Electric Power Co.

Hospital Lighting.—Settle Council have decided to put in an electric lighting installation at the local hospital at a cost of £200.

Killeshandra (Ireland).—A L.G. Board inquiry was recently held into the application of Cavan Council for powers of an urban sanitary authority with respect to the electric lighting of Killeshandra and to fix the area, charges, &c.

Launceston.—The Council have approved the plans of the proposed electricity works which the Launceston & District Electric Supply Co. proposes to erect on land adjoining the L. & S.W. Railway station.

Light Railways.—The Southend-on-Sea Light Railways (Extensions) Order has been submitted to the Board of Trade for confirmation. Objections to the Board of Trade by Sept. 14.

Liverpool.—The supply of electrical energy was interfered with to some extent on Thursday and Friday last, by the calling out by the local Strike Committee of the staff of the electric supply department.

A number of young men of good standing and position in the city, however, came forward and assisted in the running of the generating stations. With this help it was found possible to run the public and private lighting each evening and also very largely to restore the supply for the tramways.

In regard to the latter the bulk of the men remained loyal to the Tramways Committee throughout the strike, and a good service of cars was run except on Thursday, Friday and Saturday last, when the service was seriously curtailed owing to lack of current. At the time of going to press the position, however, is somewhat complicated by the fact that the Tramways Committee refuse to reinstate the 250 tramway men who went out on strike, this refusal resulting in a threat by the Strike Committee to bring about another general transport strike. The 1,500 tramway men who remained loyal have threatened to cease work if the strikers are reinstated, whilst the difficulty is further increased by the fact that the positions vacated by the disloyal men have in the meantime been filled.

As we go to press we learn that the Tramways Committee have decided to reinstate, as and when required, the 250 men who are out on strike.

Macclesfield.—The total expenditure on the tramways to March 31 was £69,575.

The annual revenue was £11,717, including £11,270 traffic receipts. The total costs were £6,944, leaving a gross profit of £4,773. After paying interest and sinking fund there was a surplus of £545 on the year's working, against £25 in 1910. 2,439,536 passengers were carried and 282,026 car-miles run; 372,379 units of electrical energy were consumed.

Maidstone.—At the meeting of the Council last week Mr. Foster Clark moved that, in consequence of the continued heavy annual loss on the light-railway undertaking, it was desirable that the Light Railways Committee should be increased so as to include the whole of the members of the Council.

Ald. VAUGHAN said he still held the view that Mr. Clark's motion was a vote of censure on the present committee. If everyone was responsible it meant that no one was responsible. The tramways were such a great benefit to the town that he did not think the ratepayers cared very much about the extra money they had to pay in rates on account of the loss involved. It was true the loss last year was about £2,600, but £2,000 of that amount went towards buying the undertaking. Was not that a good investment? For the first 19 weeks of the current year the increase of revenue from the trams, compared with last year, was £311, while there had been a saving in wages of £67. 7s. 11d. and a saving in current of £84. 10s. 4d., making a total difference of £463.

The resolution was withdrawn.

Newport (Mon.)—On Tuesday the Electricity and Tramways Committee commenced the investigation of various matters affecting the management of the undertaking, but the enquiry has been postponed until the 18th prox.

Presentation.—The staff of the Hastings Tramway Co. has presented a clock to Mr. F. B. Holliday, overhead and permanent-way engineer, on his departure from the town.

Provisional Orders Extension.—The Board of Trade have deferred the revocation of Whitworth Council's electric lighting order for three months. The Hindley electric lighting order is not to be revoked for 12 months.

Radcliffe.—The Lancashire Electric Power Co. have notified the Council of their intention to apply for a provisional order.

Royal Metal Trades Pension Society.—It is announced that the annual ball and supper of this society will take place at the Portman Rooms, London, on Feb. 1 next, the chairman on the occasion being Mr. J. Coote Garnham, of 132, Upper Thames-street, E.C. The society does an immense amount of good all over the country, and is really the only charity society in the metal and hardware trades. Mr. Garnham and the stewards invite subscriptions and donations for this special occasion.

Swansea.—Last week the Corporation adopted the agreement with the local tramways company, by which the Corporation acquires the right to purchase in 31 years' time the whole of the tramways system at construction value.

The company will work the whole of the tramways till 1942, and will pay the Corporation 2 per cent. per annum on the gross profit earned. Under the new lease the yearly rent will, after April, 1919, be £1,118. 2s., equal to 7 per cent. per annum on the aggregate expenditure of the Corporation on the section of the tramways. Artisans, mechanics and dock

Digitized by Google

labourers are to be carried on the tramways throughout the day (Sundays, Christmas Days, Good Fridays and Bank Holidays excepted) at fares not exceeding ½d. per mile or fraction of a mile, with a minimum fare of 1d. The Corporation will obtain statutory powers to construct and work certain extensions of the existing system.

Wireless Telegraph Notes.—It is announced that the negotiations which have been proceeding for some time past between the Egyptian Government and the Corporation of Lloyd's have resulted in the latter obtaining a concession for a monopoly of wireless telegraphy in Egypt. A powerful station is to be erected forthwith at Port Said, by means of which it will be possible, it is anticipated, to send messages as far westward as Malta and eastward to the Red Sea towards Aden, by October next.

COLONIAL AND FOREIGN NOTES.

Argentina.—The "Review of the River Plate" states that A company has been formed for the construction of a tramway in the district of San Isidro, joining up the lines of the Central Argentine and Central Cordoba. The capital is $500,000 m/n in shares of $100 m/n.

The Anglo-Argentine Electricity Co. have acquired the undertaking of the Franco-Argentine Electricity Co. The latter company recently acquired a controlling interest in the Anglo-Argentine Co. and now is to be absorbed by that company. More working capital is required and an early issue of shares will be made. The Anglo-Argentine Co. owns six generating stations and the Franco-Argentine four.

Australasia.—The Royal Commission on fares, &c., on the Melbourne tramways have presented their report:—

The Commission recommend that fares be revised, but, as an alternative recommendation, they suggest that the Government enter into negotiations for the purchase of all the rights up to 1916 of the Melbourne Tramway & Omnibus Co.; to constitute a tramway authority for the whole of the metropolitan area, independent of the claims or interests of any particular municipality. There would, the report continues, be little or no profit for the first year or possibly the second year, and the interest upon buildings, rolling stock, &c., might have to be capitalised until 1913 or 1914, but as the interest and sinking fund on the Tramway Trust indebtedness would cease in 1914, and £123,750 per annum would then be available for interest and sinking fund, this sum could be appropriated to the liquidation of the purchase money. The immediate purchase of the company's business is necessitated not only by reason of the desirableness of introducing sectional fares at once, but on account of the tramways extensions to the more distant suburbs, which are at present in contemplation.

Electricity Supply in Turkey.—The "Morgenpost" (Berlin) reports that negotiations for the formation of a trust company of electrical concerns in Turkey, with participation of German capital (including the Orient Bank), have almost been concluded. The amount involved is about 50,000,000 marks (about £2,500,000).

It will be remembered that some time ago Messrs. Ganz & Co., of Budapest, obtained the concession for the erection of electricity supply works in Constantinople, and a subsidiary company was formed for carrying out the work. The concession for the electrification of the tramways was obtained by the Société des Tramways de Constantinople, and in order to unite these two groups it is proposed to form a syndicate by a number of German, French, Belgian and Hungarian banks. The cost of the acquisition and construction is estimated at 36,000,000f. The concern is also contemplating the acquisition of the lighting concession from the Belgian-Hungarian group for 18,000,000f. Finally, the syndicate will acquire the rights for the execution of the project for an underground railway at Constantinople, now in the possession of the group of the Deutsche Bank, the construction of which is estimated at 36,000,000f. As soon as the licence of the latter enterprise has been granted a Belgian company will be formed which will represent at the Ottoman capital an international committee of tramway, underground railway and lighting enterprises.

Italy.—The "Gazzetta Ufficiale" has recently published a decree authorising the communal authorities of Turin to construct about 3 miles of additional electric tramway in the city; and also decrees authorising (1) the Soc. Anon. Elettrica Tramviaria Litoranea Viareggio–Versilia–Provincia di Massa Carrara, of Viareggio, to construct an electric tramway in Viareggio; (2) the communal authorities of Padua to construct an electric tramway from Padua to Abano; (3) the Elettrovie Colli Euganei to construct an electric tramway from Abano to Torreglia, passing by way of Monteortone to Tramonte.

La Paz (Bolivia).—The local electricity supply and water works were inaugurated on July 16.

Light Railways in Japan.—In a report on the trade of Japan in 1910 the acting Commercial Attaché (Mr. R. Boulter) states that the number of new proposals for light railways and electric lighting companies has continued to increase.

In August, 1910, a light railway law was put in operation in order to enforce proper control over the promotion of schemes for constructing light railways, and also to encourage the construction of such lines in order to connect minor centres of trade and production with the existing lines of railway. The nationalisation of the railways has had the effect of checking private enterprise in this direction, while the State is unable to spare funds sufficient to meet the demands for railway extension. It is hoped that this law will attract private capital to the construction of light railways. A more powerful fillip, however, to this industry was given by the bill of the 1911 session, granting subsidies to light railways. The date of the coming into force of this law is not yet determined.

It is pointed out by Mr. Boulter that, on account of the financial standing of some of the new undertakings, it is advisable for British merchants to do business with them only through firms or representatives in Japan, as the latter are in a position to ascertain whether contracts can safely be accepted.

Most of the light railways use electricity for motive power and also undertake the supply of electric current for lighting, &c. During the year a number of orders have been received for the erection of small gas-driven plants for the generation of electrical energy.

Lombardy.—In a report on the trade of Lombardy for 1910 Mr. Consul Towsey states that electrical undertakings were only slightly affected by the local depression.

The large companies that installed new plant deferred utilising some, and those whose plant was not completed delayed work so that their production should not exceed possible demands during the abnormal conditions of the market. During the year 21 new electric companies were formed with a share capital of 14,000,000 lire (about £510,000), two of them with capital of 3,000,000 and 2,000,000 lire respectively, four of 1,500,000 lire each, six with a capital varying from 250,000 to 600,000 lire, and nine with less; 32 existing companies increased their capital. Only four companies with a capital of barely 3,000,000 lire went into liquidation, and four others reduced their capital, but the companies which dissolved or liquidated were taken over or joined others. On the whole an additional sum of 50,000,000 lire was invested in electrical industries. Of the 118 companies engaged in these industries, 50 paid no dividends, but they were mostly of recent formation; nearly all the other companies declared the same dividends as in previous years, and a few increased them.

Of the 22 companies producing or selling electrical material, 11 paid no dividends, but some of these are branches of foreign firms. Of the 11 telephone companies, five paid no dividends, but some of them did not pay any in preceding years.

Spain.—The "Gaceta de Madrid" of 6th inst., contains a notice issued by the Ministry of Fomento, granting to the Soc. Anon. Iberia Concesionario de Bilbao a concession for constructing an electric railway from Porriño to Vigo.

Submarine Cable Communication with German Colonies.—It is announced by the Brunswick "Landeszeitung" that the establishment of direct cable communication between Germany and her colonies is to be hastened.

Toronto (Canada).—It is stated that the Toronto Board of Control will call for tenders (in September) from British contractors for the construction of an underground railway in the city. The cost of the line will, it is estimated, be about £800,000.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Ealing.—The accounts of the electric supply department and the report of the borough electrical engineer (Mr. J. D. Knight) for the year ended March 31 have been issued.

The output during the year increased by 55,209 units; for public lighting the supply was 1,839 units less, but the increase in private lighting was 57,048 units. The total income was £27,046 (increase £629), and there was an increase of nearly £247 in the collections from slot meters. The latter source of revenue accounts for over 5 per cent. of the gross receipts. Income from meter rents was £1,208, or £89 more. On capital account, £5,048 was spent, £8,130 was set aside out of revenue for repayment of capital, making the total repaid to date £63,912. Interest absorbed £5,153. Deducting cost of maintenance and management and charges for rent, rates and taxes, the gross profit was £15,041 14s. 2d., or 7¼ per cent. on the capital. After paying interest and sinking fund charges, audit fees and sums contributed to loans redemption fund and bad debt reserve, the net profit was £1,665. 11s. With the balance of £3,351 from last year the available balance is £5,017. Other payments bring this figure to £4,275. The reserve fund amounts to £9,955, or 4 per cent. of capital expenditure. Coal costs increased slightly. Cost of management went up by about 6 per cent., but there were 379 more consumers. The total cost per unit sold was 3·974d., compared with 3·948d. The total increase in the meters on circuit was 298, and the number of 8 c.p. lamps reached 150,507, an increase of 10,592. The total number of consumers is 4,569, or 379 more than last year, a net increase of 9 per cent. This is the largest number added in any one year since 1904. Last year there were sold to each consumer an average of 282 units, this year only 271, a decrease of 11 units per consumer. In 1906 each consumer took 359 units, so that the decrease in five years has been 88 units, or nearly 25 per cent.

Cooking by electricity having been greatly improved of late, both as regards first cost of apparatus and economy in working, it was deemed advisable to tap this large field at the earliest possible moment. "Tricity" cookers, in sizes to meet the requirements of any house, are now hired out to consumers.

Digitized by Google

Greenock.—It was reported at the last meeting of the Council that the net profit on the electricity department for the year ended May 15 was £5,520, against £3,247 in 1910.

Mr. J. C. W. Bailey, who presented the accounts, said that the power output was responsible for the largest part of the increase, but at the same time there was an increase of 21 per cent. for lighting and 13 per cent. for traction. Their policy had been shown to be a correct one, to attract large power consumers instead of allowing them to put in power plant of their own. They proposed to place £1,500 to reserve and £4,020 remained for allocation, which would be dealt with at the next meeting.

Mr. Alex. Williamson said that was the largest increase recorded in any year, and the department was now in a sound financial position. The average price of electricity to all consumers was only 1½d. per unit.

Halifax.—The income of the electricity department for the year ended March 31 was £20,952 from private consumers, £17,577 from Corporation trading departments and £1,804 from public lighting, a total of £40,333, less £1,093 for discount. With motor hire and meter rent, &c., the total receipts were £40,784.

The total expenses were £20,900, leaving a gross profit of £19,884. Interest and sinking fund charges came to £14,561, so that the net profit was £5,323. After paying part of the cost of economiser (£307) and of rotary converter (£650), and paying £693 in aid of local rate, the balance (£3,673) was placed to renewals fund. The capital expended is £260,160, an increase of £1,901 during the year. 5,964,665 units were sold (against 5,477,369), of which 2,231,182 were sold for private lighting and power, 3,668,569 for traction and 64,914 for public lighting. There are 70 street arc lamps, against 63; the maximum supply demanded was 2,900 kw., against 2,870 kw.; there are 2,000 consumers (against 1,855), with an equivalent of 188,848 8-c.p. connected (against 174,984 8-c.p.).

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1911 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 24th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1911 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

The Electricity Supply Committee of DUBLIN Corporation invite ders for supply of 750 a.c. meters (single phase) and 200 a.c. ree phase) meters. Specification, conditions and form of tender m the city electrical engineer (Mr. Mark Ruddle), Fleet-street, blin. Tenders to the Chairman of the Committee, 3, Cork-hill, blin, by noon Thursday, Sept. 7. See also an advertisement.

Tenders are invited (up to Oct. 3) for the supply of 42 miles of phone cable to the Postmaster-General's department in Vic- ia. Tender forms, &c., from the Commonwealth offices, 72, toria-street, London, S.W. See an advertisement.

Tenders are invited up to Oct. 18 for the supply of 20 coin-in-the- attachments to the Postmaster-General's Department in STERN AUSTRALIA. Specifications, forms of tender, &c., may be ained at the Commonwealth Office, 72, Victoria-street, London, . See advertisement.

The WESTMINSTER ELECTRIC SUPPLY CORPORATION invite tenders supply, delivery and erection at their Davies-street station of ery boosters and switchboards. Copies of specification, with ring and general conditions can be obtained from the Secretary the Corporation, Eccleston-place, Belgravia, S.W., to whom tenders should be sent by 10 a.m. of Sept. 12. Specification can be seen at (but not obtained from) the offices of the consulting engineers (Messrs. Kennedy and Jenkin), 17, Victoria-street, Westminster, S.W.

CLEETHORPES-WITH-THRUNSCOE Urban District Council invite tenders for the supply, delivery and laying down of a system of vulcanised bitumen distribution and feeder cables on the low-pressure three-wire d.c. system. Specification, conditions of contract and form of tender from the clerk of the Council, Mr. B. Greaves, Council offices, Cleethorpes, to whom tenders must be sent by noon of Saturday, Sept. 2.

The Council of the County Borough of WEST HAM invite tenders for (*a*) water tube boilers, (*b*) coal handling and discharging plant, (*c*) 5,000 kw. turbo-alternator, with condensing plant, (*d*) river service pipe-work, (*e*) centrifugal pumps, (*f*) 750 kw. converter (two-phase to d.c.). Specification, form of tender, &c., from Mr. H. H. Couzens, engineer and manager, 84, Romford-road, Stratford. Tenders to the town clerk, Mr. Fred E. Hilleary, Town Hall, Stratford, E., by 10 a.m. Aug. 31.

WARRINGTON Education Committee invite tenders (by noon Sept. 1) for wiring Evelyn-street Council school. Specification from Mr. T. A. Buttery, Exchange-buildings, Morley.

WEST HAM Guardians invite tenders for 12 months' electrical stores. Tenders to chairman by 11 a.m. Aug. 31.

Tenders will be received until noon Monday, Sept., 18 for the supply of Swedish, Norwegian, Finland or Russian red fir telegraph poles, for the GENERAL POST OFFICE. Forms of tender from the Controller of Stores, Mr. G. Morgan, Stores Department, G.P.O., 17 and 19, Bedford-street, London, W.C.

Tenders are invited up to Sept. 5 for the supply of (*a*) 10,000 protectors and (*b*) sundries to the Postmaster-General's Department in VICTORIA and up to Sept. 26 for the supply of telephone material and 30 miles of telephone cable to the Postmaster-General's Department in VICTORIA. Tender forms and specifications at the Commonwealth Office, 72, Victoria-street, London, S.W.

The Metropolitan Water and Sewerage Board, Albert-street, BRISBANE, Queensland, want tenders by noon Jan. 30 next for supply and erection, of one, two or three complete units, each consisting of power generating plant and pump or pumps to lift not less than 6,000,000 gallons per day. Particulars from the Secretary, and forms from the Agent-General for Queensland.

Tenders will be received on Sept. 2 at the Prussian State Railway Offices, BRESLAU, for supply of three 1½-ton electric coal-loading cranes, two (20-ton and 30-ton) transfer cranes and a fixed 3-ton revolving crane.

Tenders are invited by the Municipal Council of PELOTAS (Brazil) for a 40 years' concession for the supply of electricity for power and lighting and the establishment and working of electric tramways. Tenders to Senhor Luiz M. da S. Pennafiel, Intendencia Municipal, Pelotas, up to 1 p.m. Nov. 14. A deposit (about £300) is required with each tender, to be increased by the successful tenderer to 25,000 milreis (about £1,670). Further particulars (in Portuguese) can be seen by British contractors at 73, Basinghall-street, London, E.C.

The Municipal Council of BUDAPEST, Hungary, require tenders for the manufacture and supply of plant for a steam-driven electrical generating station, including two groups of three-phase turbo-generators (5,000 kw. each), 10,000 volts 50 cycles, boiler equipment for mechanical output of 5,000 kw. with reserve, pipeline, central switching and accessory equipments, travelling crane for engine room and coal-conveying plant. Specifications, &c., can be obtained at the Presidial Section of the Council, 9: IV., Városház-utca 16, II. 1, Budapest. Tenders by 11 a.m. Sept. 30.

Tenders will be received at the Town Hall, SYZRAN, Russia, on Oct. 14, for the construction of an electric tramway and the supply of electrical energy for lighting.

The Public Works Department, Madrid, will receive tenders on Sept. 20 for the concession for the construction of the RENTERIA electric tramway.

The time for the receipt of tenders by the Ministry of Public Works, Constantinople, for an electric power and tramway concession for JERUSALEM, is extended to Sept. 13. Specifications (in French) can be seen at 73, Basinghall-street, London, E.C.

The Municipal Commissioners of PENANG invite tenders for the supply and delivery, f.o.b. British port, of one 500 kw. steam dynamo engine or turbine with ejector condensing plant and switchgear. Specifications, general conditions and form of tender may be obtained from the consulting engineers, Messrs. Preece, Cardew & Snell, 8, Queen Anne's-gate, Westminster, S.W., to whom tenders (*in duplicate*) are to be sent by noon of Tuesday, Sept. 5.

TENDERS RECEIVED AND ACCEPTED.

Melbourne (Victoria) Council have placed a contract for a battery of Tudor accumulators, regulating switches, switchboards, &c., with Messrs. Siemens Bros. Dynamo Works at £16,487. We understand the capacity of the battery is 4,000 amperes at one-hour rate of discharge.

Erdington Council received 15 tenders for the construction of the Slade-road tramway route, together with the laying down of wood block paving outside the tramway track. The tender of Herbert Holloway (at £24,909) has been accepted.

The work of electrical equipment has been left to the Corporation of the city of Birmingham to carry out at an estimated cost of £1,356.

Haslingden Guardians have accepted the tender of Simpson Bros. for telephone and bell installation at the infirmary at £42.

Blackburn Guardians have accepted the tender of J. W. Garsden & Co. for a fire-alarm and telephone installation at the local workhouse at £192. 10s.

Among recent orders for v.i.r. wires and cables received by the Indian offices of W. T. Henley's Telegraph Works Co. were the following:—

Main underground cables in connection with the electric lighting plant for the Delhi Durbar and the twin underground cable for telephone connections in the various camps; the wiring for the lighting of several of the principal camps; also for the special illumination of the Victoria Terminus at Bombay by the Great Indian Peninsular Railway Co. on the occasion of their Majesties' visit. Orders have also been received for all the v.i.r. cables for the new mills of the Central India Spinning, Weaving & Mfg. Co. at Nagpur.

Admiralty Contracts.—The Walsall Electrical Co. have been placed on the Admiralty list for supply of small switchboards suitable for torpedo boat destroyers, cranes, accumulators, charging switches up to 100 amperes rating, ammeters up to 1,500 amperes and voltmeters up to 260 volts.

Yorkshire Boilers.—The Yorkshire Boiler Co. has received an order from the Hull & Barnsley Railway Co. for two Yorkshire boilers, 17 ft. long by 6 ft. 6 in. in diameter.

The guaranteed hourly evaporation of the two boilers is 10,000 lb. The company is completing an installation of two of their 24 ft. by 7 ft. 6 in. boilers for the Edinburgh Roperie & Sailcloth Co., the guaranteed hourly evaporation being nearly 20,000 lb. A 24 ft. by 9 ft. 6 in. Yorkshire boiler fixed during the Whitsuntide holidays was tested a few days ago, and gave an hourly evaporation of 13,670 lb. The company is also fixing a Yorkshire boiler (18 ft. by 8 ft.) at Kendal Electricity Works, which will give an evaporation of between 7,000 lb. and 8,000 lb. of water per hour.

Indian Train Lighting.—"Indian Engineering" states that Messrs. Mather & Platt have obtained an order from the South Indian Railway Co. for supply of train-lighting dynamos; Messrs. J. Stone & Co. have got the order for supply of train lighting cells; and E.M.F. (Ltd.) the contract for supply of electric ventilating fans.

On Dec. 31 last the railway had eight coaches on the broad gauge section fitted for electric lighting on Stone's system, while 331 coaches were fitted for gas lighting on Pintsch's system, and 26 vehicles were not fitted with either. On the metre gauge section (the original South Indian Railway) gas lighting is not used, but 337 coaches were fitted with electric lighting on Stone's system and 827 vehicles remain to be fitted with electric lighting.

BUSINESS NOTICES.

We are informed that Mr. A. J. Greenly, who is well known in publicity circles in the electrical industry, has joined Mr. Marcus Heber Smith, 115, Fleet-street, London, E.C. We are informed that he has a large number of original ideas for advertisement designs and trade literature. Mr. Greenly will be pleased to place at the disposal of electrical manufacturers exceptional facilities for making their advertisement copy and trade publications both forceful and attractive.

We are asked to state that Mr. David Smith has severed his connection with the Foster Engineering Co. (Ltd.).

Agents Required.—A German dynamo manufacturing firm require a London firm to act as their representatives. See an advertisement.

Patent Development.—The proprietors of patent No. 4,927/07 for "Improvements in or relating to electric furnaces" desire to make arrangements for exploiting same in this country. Communications to Messrs. Haseltine, Lake & Co., patent agents, 7 and 8, Southampton-buildings, Chancery-lane, London, W.C.

The proprietor of patent No. 13,427/06 and 880/07, for "Improvements in Dynamo electric machines," desires to make arrangements for exploiting same in this country. Applications to Messrs. Haseltine, Lake & Co., patent agents and consulting engineers, 7 and 8, Southampton-buildings, Chancery-lane, W.C.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

The Ten Republics.—This little work, which is intended to serve as an introduction to the projected series of volumes on the ten Republics of South America, by Mr. Robert P. Porter, has been recently published by Messrs. Geo. Routledge & Sons. In addition to a brief sketch of their early history, the present volume contains much interesting information regarding the economic and financial position of the various South American Republics. An interesting chapter on the Panama Canal is also included, and this is followed by separate chapters on each of the ten Republics. There are few persons better qualified to write on South America than the present author, and no doubt the projected group of volumes in Porter's Progress of Nations will contain much valuable information on the economic condition, natural resources and future development of South America, a portion of the world which should offer excellent opportunities for the employment of British capital and enterprise. The present work, which is published in paper covers at 1s., is well printed and contains 12 maps.

BANKRUPTCIES, LIQUIDATIONS, &c.

A meeting of creditors of the Havana Telephone Securities Co. (Ltd.) will be held at New Broad-street House, London, E.C., on Aug. 31.

The Canadian Electric Traction Co. (Ltd.) is being wound up voluntarily. Claims by Aug. 29 to Mr. E. H. R. Trenow, Balfour House, Finsbury Pavement, London, E.C.

The Simplex Acme Patent Fire Alarm Co. (Ltd.) is being wound up voluntarily, and Mr. W. Denton, 7, Sweeting-street, Liverpool, has been appointed liquidator.

The Fife Electric Power Co. (Ltd.) is to be wound up voluntarily. The liquidator is Mr. Jas. Watt, 28, Charlotte-square, Edinburgh, where a meeting of creditors will be held on Sept. 1.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*NOTE.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

June 27, 1911.

14,994 BINGHAM. Means and apparatus for duplex wireless telegraphy.
14,999 BACHE. Experimental apparatus for intuitive electric instruction.*
15,008 WATKINSON & PAYNE. Shade-holders for incandescent and electric lights and the like.
15,038 MIDGLEY & VANDERVELL. Dynamo-electric machines.
15,039 MIDGLEY & VANDERVELL. Automatic switches or cut-outs for use in charging secondary batteries from dynamo-electric machines.
15,052 RANSFORD. (Samuel P. Thrasher, U.S.) Electric signalling apparatus.*
15,054 DENISSEL. Electric heating apparatus.*

June 28, 1911.

15,072 BARRON & BARRON. Preparation or solution for the deposition of metals.

SPECIFICATIONS PUBLISHED.

1910 Specifications.

8,031 B.T.-H. Co. (G.E. Co.) Tungsten and the manufacture thereof.
12,194 Johnson. Electric switch.
13,274 Hamilton & Ferranti. Electrical time switches.
14,334 Mathieson. Automatic contact device for use in connection with the overhead equipment of electric tramway installations.
4,625 Electric and Ordnance Accessories Co. & Collins. Slow-motion devices for use in connection with electric controllers, starting switches, and the like.
4,766 Compagnie de l'Industrie Electrique et Mecanique. Combined speed and current regulators for dynamo-electric series machines. (19/5/10.)
4,851 Adams mfg. Co. (Cutler Hammer Mfg. Co.) Controllers for electric motors.
5,004 Thomson. Construction of small or pocket electric lamps.
5,134 Rehrup. Magneto-ignition devices for internal-combustion engines.
5,143 Klostermann. Arc lamps. (26/6/09.)
5,356 Thomas. Control of series wound dynamo-electric machines.
5,414 Christian. Trolley poles for electric traction on the overhead conductor system.
5,415 Akt.-Ges. Brown, Boveri et Cie. Voltage regulation of dynamo-electric alternating current machinery. (10/7/09.)
5,423 Newton. Dynamo-electric machines for producing constant voltage.
5,619 Lambot. Automatic electric recording devices.
5,695 White. Electrically-controlled ejector vacuum-cleaning apparatus.
6,711 Quint. Enclosed arc lamps of the inverted type.
6,724 Pechin. Couplings for arc lamps.
6,869 Cerbetani. Wireless-operated electrical signalling, indicating, or like means. (24/2/10.)
6,466 Paton. Interlocking switch box for electric lighting or power transmission cables.
6,559 Clarke, Chapman & Co., & Moysey. Electric transmission means for use as or in helm indicators or in telemotor arrangements for steering-gear and the like.
7,690 Ashworth. Trolley poles for electric tramways.
8,136 Veritys, Ltd., & Pipkin. Electrical heaters or stoves of the radiator kind.
8,217 Stevenson & Williams. Raising and lowering arc lamps or other fittings suspended in central carrier frames.
9,969 Higgins. (Higgins.) Electrolytic reduction of organic bodies.
10,182 Electric & Ordnance Accessories Co. & Collins. Electrical switches. (Addition to 24,373/09.)
10,522 Brooks & Alston. Electric contact breakers for use in connection with the ignition systems of internal-combustion engines.
11,729 John & Berry. Galvanic battery.
11,794 Kirkland. Power systems employing prime movers.
12,717 Milch. Speed regulation of induction motors. (1/10/09, addition to 12,326/08.)
12,777 Massip. Electric furnaces and the manufacture of steel. (2/10/09.)
13,506 Dibgdon. Device for protecting the cars and trolley-wire on electric railways and tramways. (Cognate application 25,462/10.)
13,238 Hirst & Archer. Electric heating apparatus.
14,421 Smith. (Huth.) Receiving method for wireless telegraphy
25,012 Sefton-Jones. (Oesterreichische Daimler-Motoren Ges.) Collectors for overhead conductor electric-traction systems.
25,634 Schmidt. Self-regulating arc lamps for projection.
26,045 Krannichfeldt. Producing electric incandescence bodies.
26,836 Field & Ferranti Limited. Electric heaters.
27,176 Apoznanski. Electric accumulator plates.
27,407 Rosculet & Constantinescu. Vapour incandescent lamps.
27,652 Alwies. Street or station indicators for electric trains, tramcars, and the like. (26/11/09.)
28,177 Juston & Bunzli. Magneto-electric current generators. (10/3/10.)
28,246 Gray. Governing or controlling devices for dynamos.
28,320 Ray. Guide-sheaves for ships' telegraphs and the like.
28,724 Frankenburg & Sons, Ltd., & Fleming. Electric lighting.
29,727 Crompton & Co., McFarlane, Burge & Williams. Controlling electrically-operated driving systems.
29,810 Wolff. Automatic distributor for electricity.
28,994 Frisby. Electric-current gauges or apparatus for measuring the strength of electric current.

1911 Specifications.

790 Sauerbrey. Ascertaining the position of the current distributor in electro-magnetic ignition devices for explosion engines. (12/1/10.)
1,848 Mowbray. Thermal electric fire alarms.
2,111 Reisz & Strauss. Relay for undulatory currents. (30/3/10.)
2,369 Schulz & Eyermann. Homopolar or acyclic dynamo-electric machines.
2,632 Bellini & Tosi. Antennæ of wireless telegraphy and telephony. (10/2/10.)
3,028 B.T.-H. Co. (G.E. Co.) Mounting of electric conductors more particularly filaments for incandescent electric lamps.
3,533 Schatzl. Electric furnaces.
5,806 Girdlestone & Thorkelin. Arc lamps.
3,859 Mazellier. Electric sparking plug. (17/2/10.)
3,891 Korting & Mathieson Akt.-Ges. Enclosed arc lamps. (21/2/10.)
3,949 Girardeau. Sender with direct excitation for radiotelegraphic plants. (30/7/10.)
4,008 Klupathy & Berger. Apparatus for generating sound-waves and like vibrations in water.
4,524 Pritchett. Electric accumulator boxes. (Addition to 15,425/10.)
5,521 Sumner. Current graduation devices or resistances applicable for electric lighting or heating.
5,813 Hultman. Apparatus for manufacturing conduits for underground cables. (9/4/10.)
6,736 and 6,737 Siemens Bros. & Co., & Riber. Fixing and insulating contact springs for electrical apparatus.
6,823 Siemens & Halske Akt.-Ges. Recording intervals of time between the passage of trains on a track and the speed of the trains. (30/4/10. Addition to 376/10.)
7,103 B.T.-H. Co. (G.E. Co.) Boron compounds and methods of producing the same.
7,511 Krannichfeldt. Insulating the twisted ends of electric wires.
7,668 Allgemeine Elektricitats Ges. Electric voltage regulators. (26/3/10.)
8,392 Siemens Bros. Dynamo Works & Koettgen. Ventilation of dynamo-electric machines.
8,484 Martyn. Bonding devices for electric cables and electric fittings. (Divided application on 9,121/10. 23/4/.)
9,941 Spezialfabrik fur Aluminium-Spulen-und Leitungen Ges. Production of electrically insulating layers or coatings on metal.
9,942 Allgemeine Elektricitats-Ges. Coinfreed mechanism. (23/4/10.)
10,113 Siemens Bros. Dynamo Works. (Siemens-Schuckertwerke Ges.) Non-interchangeable electric fuses.
10,238 Telephon Apparat Fabrik E. Zwictusch & Co. Ges. Method of connection of lines in automatic telephone exchanges.
10,816 Chamberlain & Hookham, Ltd., & James. Electricity motor meters.

COMPANIES' MEETINGS AND REPORTS.

ABERDEEN SUBURBAN TRAMWAYS CO.—The profit earned during the past half-year was £1,443, and the balance at credit of profit and loss account is £3,233. The directors propose to add £1,800 to renewals and depreciation account and to pay a dividend of 2½ per cent. for the past year (£780).

BRITISH CONTINENTAL ELECTRICITY CO. (LTD.)—The directors report for the year ended April 30 states that during the year 179 new installations have been connected, while the number of 8 c.p. lamps added during the period has been 1,545. Towards the end of the year a contract for the public lighting of the village of Poggio was entered into on favourable terms, as also a contract to supply power to San Remo Corporation. After writing off £162. 3s. 4d. depreciation in respect of furniture, tools, meters, &c., and £177. 1s. 4d. depreciation of plant and stock, the balance (including amount from last year) is £2,315. 19s. 8d., a sum sufficient to pay a substantial dividend on the ordinary shares after paying in full the preference dividends due to date. As, however, this balance has been temporarily absorbed by further capital expenditure, rendered necessary by the continued growth of the business, the directors recommend that it shall be again carried forward pending a further issue of capital; £171. 13s. 1d. has been carried to a suspense account pending arbitration in respect of a power contract entered into by the company, and the directors anticipate that they will eventually be able to credit revenue account with a substantial award; £804.6s.7d. has been spent on capital account during the year.

BROWN, BOVERI & CO., A.G. (BADEN).—The net profit for the past year amounted to 2,300,031 fr. (£92,003), against 2,142,122 fr. (about £85,684) in 1909-10, and it is proposed to pay a dividend of 7 per cent., against 8 per cent. The general conditions of the electrical engineering industry are stated to have been not entirely satisfactory, but the outlook is considered good, all departments being well supplied with orders. The technical problems with regard to railway electrification are considered to have been settled, but it is not thought that any great amount of business will result until some main electrical line shows good financial results in working. Brown, Boveri & Co., of Mannheim, paid a dividend of 4 per cent., the Compagnie Electro-Mécanique (Paris) 10 per cent., the Tecnomasio Italiano Brown, Boveri (Milan) 4 per cent., and the Aktiesels-kabet Norsk Elektrisk & Brown, Boveri (Christiania) 5 per cent. The parent company has now formed the Austrian Brown, Boveri Works

Digitized by Google

Vienna, having a capital of 4½ million kronen, of which 1½ million kronen are held by the Swiss undertaking.

GREAT WESTERN RAILWAY CO.—At the recent meeting the chairman (Viscount Churchill) stated that powers had been granted to the London Electric Railway Co. for the extension of their Baker Street and Waterloo line from Edgware-road to Paddington Station, and arrangements were being made to put the work in hand at once, while the construction of the Ealing and Shepherd's Bush line would also be proceeded with without delay now that the Central London Co.'s bill for the construction of a short extension of line at Wood-lane to connect with the authorised Great Western line from Ealing to Shepherd's Bush only awaited Royal assent.

JANDUS ARC LAMP & ELECTRIC CO. (LTD.)—At the meeting last week the chairman (Mr. E. N. Galloway) moved the adoption of the report which recommended payment of a dividend for the past year of 10 per cent. and the transfer of £2,500 to reserve.

KALGOORLIE ELECTRIC TRAMWAYS (LTD.)—Gross receipts for 1910 amounted to £43,004, compared with £45,266 for the previous year, and the net profits were £15,199, against £16,575. The directors regret to report the decrease in traffic receipts and nett profits. The rush to the Bullfinch district, which took a large number of the mining population and considerable money from Kalgoorlie, had its effect on the general trade of the district and the tramway receipts suffered in consequence. The construction of the trans-continental railway is likely to be commenced next year, and it is hoped that the completion of this line will have a beneficial effect on the prosperity of Kalgoorlie by opening up the country to the east. Until improved conditions are brought about, either by the railway or by the discovery of new mines, no increase in traffics can be expected. In the meantime every possible effort is being used to reduce working expenses. During the year 624,790 car-miles were run, against 631,212 in 1909, and 2,793,216 passengers, against 2,936,411, were carried. The earnings per car-mile were 16·45d., against 17·16d. in 1909, while expenses per car-mile amounted to 10·13d., against 10·29d. The expenses per cent. of earnings were 61·57 per cent., against 59·99.

NORTH-EASTERN RAILWAY CO.—At the meeting last week the chairman announced that the question of the electrification of the Shields to Newcastle line was receiving attention.

PERTH (W. AUSTRALIA) ELECTRIC TRAMWAYS (LTD.)—Gross receipts for 1910 amounted to £68,799, compared with £74,649 for 1909; the profit was £26,702, against £30,161. This decrease was due to the strike of motormen and conductors in July and August. The strike was the result of an application to the Arbitration Court by the men, at the instance of professional agitators, who, when the award was obtained, put an interpretation upon it which induced the men to make unreasonable claims upon the company, which were resisted; the men again appealed to the Court, and not being satisfied with its decision, elected to strike.

The question of the purchase of the company's undertaking, either by the City Council or by the State, has been a matter of local discussion. The board, therefore, deemed it wise to fortify themselves with the best legal and technical advice on the concessions and agreements, with the result that they are satisfied that the position of the company is a strong one. The feeling in Perth is that the tramway undertaking should be acquired either by the City Council or by the State and the latter view appears to predominate. The directors have intimated to the Mayor that they would advise the shareholders to accept £500,000. From the shareholders' point of view it would be better if the company were allowed to work the tramways for the full period of 29 years, but in view of the pressure of public opinion, the directors have every reason to believe that a definite offer to purchase will be made in the near future. After paying debenture interest, &c., and adding £1,056 brought forward, £10,054 was available. The preference dividend absorbed £6,000, and the directors recommend payment of a dividend on ordinary shares at the rate of 2½ per cent., £2,500. £1,000 is placed to reserve and the balance (£554) carried forward.

NEW COMPANIES, STATUTORY RETURNS, MORTGAGES AND CHARGES, &c.

NEW COMPANIES.

ARDROSSAN AND SALTCOATS ELECTRIC LIGHT AND POWER CO. (LTD.) (7,959)—Reg. in Edinburgh Aug. 11, capital of £20,000 in £1 shares, to carry on the business of an electric light, power and heat supply company. First directors: G. Balfour and A. H. Beatty. Reg. office: 63, Castle-street, Edinburgh.

SKELMORLIE ELECTRIC SUPPLY CO. (LTD.) (7,960)—Reg. in Edinburgh Aug. 11, capital £10,000 in £10 shares, to acquire the business of the Skelmorlie Electrical Supply Co. Private company.

THOMAS R. CARPENTER (LTD.) (117,300)—Reg. Aug. 17, capital £5,000 in £1 shares, to carry on in Birmingham or elsewhere the business of manufacturers of and dealers in chandeliers, electric light and gas fittings, &c. Private company. T. R. Carpenter is first director.

WHITFIELD FAN CO. (LTD.) (117,321)—Reg. Aug. 18, capital £2,000 in £1 shares, to carry on the business of electrical, ventilating, mechanical and heating engineers, manufacturers of electric and belt-driven fans, &c., to acquire the business carried on at Shipley (Yorks) as the Whitfield Fan Co. First directors: J. Whitfield, J. Bolton and J. Bailey.

STATUTORY RETURNS.

ANCHOR CABLE CO. (LTD.)—In return to June 6 capital is £250,000 in £10 shares. 6,500 shares taken up. £10 per share called up on 4,600 and £5 per share on 1,500. £53,500 paid. £4,000 considered as paid on 400. Mortgages and charges: £50,000.

BRITISH ELECTRIC AUTOMATIC MACHINES (LTD.)—Return to July 28 gives capital as £150,000 in 200,000 preference and 400,000 ordinary shares of 5s. each. 30,000 preference and 5,280 ordinary shares taken up. 5s. per share called up on 10,000 and 1s. per share on 20,000. £3,259 paid, leaving £241 in arrears. £1,320 considered as paid on 5,280 shares. Mortgages and charges: Nil.

ELECTRICITY SUPPLY CO. FOR SPAIN (LTD.)—According to return to July 4 capital is £105,000 in 20,000 preference shares of £5 each and 19,900 ordinary and 100 founders' shares of 5s. each. 17,330 preference, 19,900 ordinary and 100 founders' shares taken up. 5s. per share called up on 19,900 ordinary. £4,975 paid. £86,675 considered as paid on 17,330 preference and 100 founders'. Mortgages and charges: £131,400.

ELECTROMOTORS (LTD.)—According to return to June 1, capital is £50,000 in £1 shares. 42,370 shares taken up. £1 per share called up. £39,195. 4s. paid, leaving £3,174. 16s. in arrears. Mortgages and charges: Nil.

EUROPE AND AZORES TELEGRAPH CO. (LTD.)—According to return to July 12 the capital is £200,000 in £10 shares. All shares taken up. £10 per share called up on 14,432. £144,320 paid. £55,680 considered as paid on 5,568. Mortgages and charges: Nil.

HESWALL ELECTRIC LIGHT CO. (LTD.)—In return to May 31, 1911, capital is £1,500 in £1 shares. 1,225 shares taken up. £1 per share called up. £1,225 paid. Mortgages and charges: Nil.

GORSEINON ELECTRIC LIGHT CO. (LTD.)—Return to June 3 gives capital as £4,000 in £1 shares. 2,000 shares taken up. £1,998 paid. Mortgages and charges: £800.

MORTGAGES AND CHARGES.

DAWLISH ELECTRIC LIGHT AND POWER CO. (LTD.)—Debenture dated July 25, 1911, to secure £2,000, charged on company's undertaking and property, present and future, including uncalled capital. Holders: The Capital & Counties Bank.

CITY NOTES.

MEMORANDA (Aug. 24).—**Bank rate 3 per cent.** (March 9, 1911). **Price of silver,** 24⅝**d. per oz. Consols** 78⅛—78⅜ **for money and for accounts. Consols Pay Day, Sept. 1; Stock and Shares Continuation Days, Aug. 29 and Sept. 12; Ticket Days, Aug. 30 and Sept. 15; Pay Days, Aug. 31 and Sept. 14; Mining Shares Carry Over Days, Aug. 28 and Sept. 11.**

PRICES OF METALS (London).—*Copper*, cash, 56⅝; three months, 57. *Lead*, English, 14¾—14⅞; Foreign, cash, 14⅝; three months, 14¾. *Spelter*, 27½—28. *Tin*, English, 191—193; Foreign, cash, 189½; three months, 187. *Iron*, Cleveland, cash, 47/6, three months, 48/4.

BAHIA TRAMWAY, LIGHT AND POWER CO. & CIE. D'ECLAIRAGE DE BAHIA.—The earnings of these companies for July were £14,600 (increase £766). The aggregate from Jan. 1 is £91,533 (increase £14,004).

KALGOORLIE ELECTRIC TRAWWAYS (LTD.)—Traffic receipts for July were £3,320. Aggregate from Jan. 1 £23,784.

MACKAY COMPANIES.—The regular quarterly dividend of 1 per cent. on the preferred shares and the regular quarterly dividend of 1½ per cent. on the common shares in the Mackay Companies will be paid on Oct. 2 to shareholders of record as they appear at the close of business Sept. 9. The transfer books will not be closed.

MADRAS ELECTRIC TRAMWAYS, 1904 (LTD.)—Traffic receipts for the fortnight ended Aug. 15 were R.2,2619 (increase R.2,164). Aggregate from Jan. 1 R.330,565 (increase R.27,913).

STEWARTS & LLOYDS (LTD.)—The directors have declared interim dividends for the half-year ended June at the rate of 6 per cent. on the preference and 10 per cent. on the preferred ordinary shares.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee has ordered £200,000 5 per cent. first mortgage debentures of the *Birmingham Tramways Co. (Ltd.)* to be quoted in the official list. The Committee have been asked to grant quotations to a further issue of 37,900 £1 fully-paid ordinary and 227,011 £1 7 per cent. preference shares of *Marconi Wireless Telegraph Co. (Ltd.)*.

NOTES.

The British Association.

ONCE more the members of the British Association are gathered together, and this time the meeting takes place at Portsmouth. Sir WILLIAM RAMSAY in his Presidential Address on Wednesday evening dwelt, among other matters, on the husbanding of our coal supply. The prominence given in the daily Press to his Address should certainly result in greater attention being devoted to this important subject. Yesterday the various sections met to hear their respective Chairmen's addresses. The number of members of all classes attending this year's meeting is returned as 1,200, and if only by reason of the proximity of the dockyards and Southsea the occasion will certainly be enjoyable. Of late years there has been a falling-off in the quality of Papers read and the reasons are not far to seek, but it is to be hoped that this year will see a welcome revival.

IN his address to Section A, Prof. H. H. TURNER pleads for the amateur, but his conception of the amateur is not that generally held by the man in the street. As a rule the amateur is a person of whom it may be said that "a little learning is a dangerous thing." By the professional he is regarded with something akin to contempt, and because of the old rule that a thing which costs nothing is not worth having, his advice is seldom sought and still more seldom taken. Amateur engineers, doctors, lawyers, and even sailors and soldiers, we always have with us, but generally they are not to be compared with the professional. Prof. TURNER'S amateur is, however, quite a different creature. His amateur is the man who, with no pay and often with no hope of reward, gives up his time and means to the prosecution of research. If this is the true meaning of the word, then it can only be said that there would be little progress if it were not for the amateur, and that everything possible should be done to encourage him.

Supply Stations and Strikes.

ATTENTION was called in our Notes last week to the necessity for legislation in connection with breaches of contract by workmen engaged in electricity supply and kindred industries, and although something will undoubtedly be done in this direction, yet time must necessarily elapse before any proposals can be embodied in an Act of Parliament. In the meantime the danger remains, and no one will dispute that it is very real. Since, moreover, legislative precautions for dealing with such an emergency are, according to present indications, not likely to prove a complete solution of the problem, it behoves electric supply authorities, and particularly municipalities, to take steps whereby continuity of supply shall be maintained in the event of a sudden stoppage of work by employés.

THE citizens of Liverpool, profiting by experience, have enrolled a number of volunteers who are prepared to come forward in an emergency and take up various duties in much the same way as was done by certain public-spirited persons during the recent strike. This example is commended to the notice of supply authorities, who, by

Digitized by Google

following it, would thus be in a position to fulfil their obligations to the public, for a time at all events, and incidentally would place themselves in a much stronger position than they have ever held before. Since, also, the supply of fuel is liable to be seriously interfered with, even at 24 hours' notice, as in the recent railway strike, greater attention will doubtless be paid in future to maintaining a larger storage of coal. If reports in the daily Press are correct, many electric supply stations would have been in difficulties if the dislocation of railway traffic had occurred during the winter months.

Electricity Supply at Glasgow.

In analysing last week the accounts of the Glasgow Corporation Tramway Department we set out in detail the various items in the total cost of generating the electrical energy supplied to the cars. It is interesting to compare these figures with those contained in our analysis, on another page of this issue, of the accounts of the Corporation's electric supply undertaking for the year ended May 31st last. These accounts show that the undertaking is making excellent progress, nearly 1,700 new consumers having been obtained during the past 12 months, whilst the sales of energy to private consumers have increased by 4¼ million units. The low charges for current have, doubtless, done much to popularise the use of electricity and to bring about the above result, and in this connection domestic consumers, who for some time have obtained current for lighting at 3d. per unit, can now have energy for cooking, heating, &c., at 1d. per unit without the inconvenience of separate wiring. This scheme was only introduced last October, but by May of the present year it had been adopted by 300 consumers. Another feature of the supply is that no less than 7 million units, out of a total of 39 million sold to private consumers, were supplied at ½d. per unit.

In regard to the cost of generation, it will be noticed that salaries and wages are 0·09d. per unit sold and per unit sent out respectively in the case of the electric supply and the electric tramway power stations; whilst the cost of oil, waste, water, &c., is 0·01d. as against 0·02d. in the two cases. It is also interesting to observe that the cost of fuel is 0·19d. with a 19·8 per cent. load factor in the case of the electricity undertaking, and 0·13d. with a 39·7 per cent. load factor in the tramway power station; whilst the interest on the capital outlay is, per unit, approximately inversely proportional to the load factors, as might be expected. The tramway report states that the total cost of the tramway supply, including depreciation, is 1·17d. per unit sent out to sub-stations; so that, in view of the above figures, advocates of separate power stations would have difficulty in proving any economy from that arrangement, although local circumstances might sometimes point to its desirability.

The Education of Engineers.

If there was one thing that the recent Education Conference made clear it was the extraordinary diversity of opinion that exists between teachers and engineers as to the best method of training men for the profession of engineering. It is unfortunate that this should be so, for it must lead to uncertainty in the minds of parents who desire that their sons shall become engineers. In this connection we publish on another page of this issue a short account of the courses provided at Faraday House. These courses possess three great advantages: they are not designed to prepare the student for a particular degree, but rather to teach him the general principles of engineering; they provide an equal mixture of sound theoretical and practical training; and they give good promise of employment, as soon as he leaves the institution, to a student who has passed through them meritoriously. The training given appears to be eminently suited to the end it is desired to attain, and it is refreshing to know that such an institution can be successful, even though it does not indulge in the fascinating pastime of degree-hunting.

"Elektrotechnische Zeitschrift."—The offices of this journal have been moved to Berlin W. 9., Linkstrasse 23/24.

Electric Traction in Norway.—A recently issued report of the Committee on the electrification of Norwegian Railways states that a large amount of money can be saved by applying electric traction to the new lines which are being constructed. The only actual railway project imminent is the conversion of the Christiania–Drammen railway, but several private lines are already electrified. The general report of the Committee is in favour of a complete investigation into the whole question of converting the Norwegian lines. In view of the conversion of the railways, a large international combination of water-power installations in Scandinavia has recently taken place, with a capital of £2,000,000, in which three well-known German electric manufacturing firms are interested.

The Danger of Imperfect Earth Connections.—While the importance of earthing secondary circuits in order to render them safe against the possibility of accidental connection with high-tension wires is fairly understood, there is perhaps an insufficient appreciation of the necessity for having earth connections in perfect condition. A poor earth connection is worse than none at all on account of the sense of false security which it inspires. Whenever there is a connection between high-tension lines and ordinary lamp circuits there is a dangerous condition, owing to the possibility of some person's body completing the connection between the high-tension lines and earth. The possibility of such accidents is increased when in addition to the accessible lamp cords and switches there is added an earth wire running down a pole to an imperfect earth, the wire being exposed so that it is possible for persons or animals to come in contact with it. The "Electrical World" points out that earth rods or plates in dry, sandy or rocky soil are of very uncertain value and should not be depended upon. Wherever possible, earth connections to water-pipes should be secured. The ineffectiveness of earth connections in dry sandy, rocky soil has been many times tested, and a most deplorable practical test of the poor quality of such connection was recently made on a system operating in northern Michigan. The company earthed its secondary wires to a guy wire, the anchor of which was thought to be buried in the ground far enough for a good earth connection to be secured. An accidental connection between high-tension and low-tension wires occurred, thereby rendering the guy-wire earth connection alive, owing to there being insufficient contact with moist earth to cause the fuses on the high-tension line to open. A calf was killed by coming in contact with the guy wire, a veterinary surgeon coming along later to investigate the cause of the calf leaned against the guy wire and was also killed.

Wireless Telegraphy and Storm Warnings.—The sixth annual report of the Meteorological Committee of the Treasury, which was issued recently, states that during the year ending March last, 3,955 wireless reports were received from Atlantic liners, and were of great assistance to the forecaster. On January 28 a message which came to hand about noon showed that at 7 a.m. on that day a deep depression was in existence at some distance to the west of Ireland. Storm warnings were issued immediately to the west coast of Ireland, and in the course of the evening or night strong gales were experienced there.

The Hygienic Aspects of Lighting.—In a recent issue of the French official gazette "L'Officiel," it is announced that a committee dealing with the hygienic aspects of illumination has been appointed by the Minister of the Interior in France. The objects of the committee cover a wide ground, including the general effects of illumination on health, the framing of simple rules as to the best means of applying customary systems of lighting to various industrial operations, the nature and causes of short sight and impairment of vision, and their connection with defective living conditions, the study of methods of measuring illumination, &c. In investigating these different questions conjointly the committee should accomplish much valuable work. In the past the difficulty has sometimes been that recommendations on lighting were made by those interested primarily in physiological and hygienic questions, but without an adequate knowledge of the measurement of illumination, or vice versa. It is therefore satisfactory to observe that this committee receives the support of a number of prominent authorities on hygienic matters, gas and electrical engineers, inspectors of factories and others interested in various aspects of industrial lighting.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. D. Owen contributes an article on "The Pressure of Radiation."

The British Association meeting at Portsmouth opened on Wednesday evening when Sir Wm. Ramsay delivered his presidential address. Abstracts of this address, of the address of Prof. H. H. Turner to Section A (mathematical and physical sciences), and that of Prof. J. Walker to Section B (chemical) are given in this issue.

Standard tables for bare copper cables have been issued by the Bureau of Standards, Washington.

We give an account of the electrical work carried out at the Physikalisch-Technische Reichsanstalt during the past year.

We describe the Corcovado electric railway, in the neighbourhood of Rio de Janeiro.

The Faraday Lecture of the Chemical Society was delivered by Prof. T. W. Richards, the subject being "The Fundamental Properties of the Elements."

We analyse the accounts of the Glasgow Corporation Electricity Department for the year ended May 31st last.

The report on another page of the meeting of Liverpool Electricity Committee is of special interest, and throws a strong light upon the action of the tramway men as well as of the electricity department employés during the recent troubles in that city.

An abstract of the Census of Production for the year 1907 is given in another column.

A report of the proceedings at the meeting of the Association of Chambers of Commerce appears in another column.

OBITUARY.

L. E. Eschbæcher.—We regret to record the death, at Basle, on the 11th ult., of M. Louis Emile Eschbæcher, a former vice-director of the Bureau International des Telegraphes, at the age of 79. M. Eschbæcher was born at Hochfelden in Alsace on August 25, 1832, and entered the French Telegraph Service in the fifties. He spent several years in Algeria in the sixties, supervising the establishment of the telegraph system in that country, and joined the French Military Telegraph Service during the Franco-German War. He gained the cross of the Legion of Honour on the Battlefield of St-Privat, near Metz. After the war he became Inspector of Telegraphs at Besançon and later become Chef de Bureau at the Central Telegraph Administration in Paris. He was French delegate to the International Telegraph Conference of London (1879). He was appointed Secretary to the International Telegraph Bureau at Berne in 1885, and took a prominent part, as Secretary General, in the International Telegraph Conferences of Berlin (1885), Paris (1890), Budapest (1896), and London (1903). He was appointed Vice-Director of the International Bureau in 1897 and retired in 1905.

A. E. Preddle.—Mr. Albert E. Preddle, son of Mr. F. T. Preddle, Secretary of the Direct Spanish Telegraph Company, died at the Eastern Telegraph Company's station at Carcavellos, Lisbon, on Sunday, Aug. 27, of typhoid fever. The funeral took place at the English cemetery at Lisbon on Aug. 29, the family being represented by the Marquis of Villalobar, K.C.V.O., Minister Plenipotentiary to H.M. The King of Spain. The deceased was 23 years of age, had been at Carcavellos three years, and was greatly esteemed by all who knew him for his bright and amiable disposition.

We wish to be associated with the condolences to Mr. and Mrs. Preddle and the family.

PERSONAL NOTES.

Sir William Crookes, O.M., F.R.S., begs his friends to accept his grateful thanks for kind inquiries during his serious illness, and hopes before long to reply personally to their letters, which are too numerous to admit of immediate attention.

Mr. Wm. G. Hunter notifies us that he has resigned his position as advertising manager of the incandescent lamp department of the British Thomson-Houston Co., and is at liberty to enter into negotiations with any electrical firm, preferably an undertaking marketing an electrical incandescent lamp.

APPOINTMENTS VACANT AND FILLED.

An electrical engineer is wanted familiar with electrical and mechanical design of d.c. motors. Applicants must be technical graduates and read and speak English. See an advertisement.

One or two draughtsmen are wanted by a large electrical firm. Must be used to switchgear design, &c. See an advertisement.

An instructor is wanted for classes in telegraphy and telephony (City and Guilds syllabus) for the Wimbledon Technical Institute. Applications to the Principal, Gladstone-road, Wimbledon. See advertisement.

A competent battery mechanic, used to erecting and maintaining Tudor type secondary batteries, is wanted for South Africa. Commencing salary £30 per month, with three years' agreement. Applications to the Victoria Falls and Transvaal Power Co., 2, London Wall-buildings, London, E.C. See also an advertisement.

Test room assistants are wanted for adjusting and calibrating a.c. and d.c. ammeters, voltmeters and wattmeters. See advertisement.

A shift engineer is required for the electricity works of the Public Works Department of Southern Nigeria for two tours each of 12 months' residential service, with possible extension. Salary £250, rising to £300 per annum. Applications at once to the Crown Agents for the Colonies, 4, Whitehall-gardens, London, S.W. Further particulars are given in an advertisement.

An assistant lecturer and demonstrator on physics is required at the Battersea (London) Polytechnic. Commencing salary £120 per annum. Particulars from the Secretary.

Mr. F. Swarbrick, of Leigh, has been appointed engineer and manager of the Galway Electric Co.

Mr. C. W. Jackson has been appointed chief assistant engineer at the Urban Electric Supply Co.'s Grantham electricity works, in place of Mr. F. H. Brandreth, who has been appointed as resident manager of the same company's electricity supply undertaking at Stamford.

Mr. W. J. Carter, senior charge engineer at Oldham Corporation electricity works, has been appointed chief assistant electrical engineer at Batley electricity works.

EDUCATIONAL NOTICES.

University of St. Andrews.—The 500th anniversary of the foundation of this University, which will occur this month, will be celebrated by the conferring of a number of honorary degrees. The degree of Doctor of Laws will be conferred among others upon the following :—Dr. E. W. Hobson, F.R.S., of Cambridge ; Prof. H. Lamb, F.R.S., of Manchester ; Prof. J. J. Larmor, Sec. R.S., of Cambridge ; Major P. A. MacMahon, F.R.S., of London ; Prof. R. Meldola, F.R.S., of London ; Prof. W. H. Perkin, F.R.S., of Manchester ; Prof. W. J. Pope, F.R.S., of Cambridge ; Dr. A. Schuster, F.R.S.; Sir J. J. Thomson, F.R.S., of Cambridge ; and Prof. W. Voigt, of Gottingen.

University College of North Wales.—At this college a systematic course of instruction in electrical measurements and practical electricity is provided for students proposing to enter the electrical engineering profession. The physical laboratory is well equipped for practical work and the fee for the ordinary course is £17. 1s. per session. The next session commences in October.

University of Manchester.—Prospectuses giving particulars of the lectures and laboratory courses in physics, preparing for both the ordinary and honours degrees, will be forwarded on application to the Registrar. Prof. Rutherford will meet intending students on Oct. 3.

University College, Nottingham.—The engineering department of the college provides thorough courses of instruction for the London University B.Sc. degree examinations and for college and other diplomas in engineering and mining. The session begins Oct. 2. Prospectus from the Registrar.

University of Durham.—Armstrong College, Newcastle-upon-Tyne.—The 1911-12 session commences Sept. 25. There are departments of mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars may be obtained from the secretary, Mr. F. H. Pruen, M.A.

University of Bristol.—Prospectuses and particulars of the faculties of arts, science, medicine and engineering (civil, mechanical, electrical and motor car) and of the secondary training department, day training colleges, evening classes, halls of residence, scholarships and bursaries will be sent on application to the registrar, Mr. James Rafter. The session in the faculty of engineering commences Sept. 15 and in faculties of arts, science and medicine on Oct. 2.

University of London, University College.—The new session commences on Monday, Oct. 2. There are complete courses of study, extending over three years, in mechanical, electrical, civil and municipal engineering. Students desirous of entering the faculty of engineering, with the view of taking a full degree or diploma course, must have passed the matriculation examination, or some other examination accepted in its stead. There are also special diploma courses, and provision is made for post-graduate work and research. Intending students should communicate with the Provost as soon as possible, and full particulars may be obtained on application to the secretary, Mr. Walter W. Seton, M.A., Gower-street, W.C.

University of London, King's College.—Complete courses of study, extending over three or four years, are provided by this college in civil, mechanical and electrical engineering for engineering degrees of the University of London, and for the diploma and certificate of the college. The four years' course provides, in addition to the academic training, opportunity for practical training in works. Full information may be obtained from the Dean or the Secretary, King's College, Strand, London, W.C.

City and Guilds Technical College.—This college provides a scientific training for students preparing to become electrical and mechanical engineers or chemists, and for engineering pupils who desire to supplement their practical training by a two years' course of instruction in the principles of engineering science. There are also arrangements for three-year courses in engineering. Particulars at the college, Leonard-street, City-road, London, E.C., or from the City and Guilds of London Institute, Gresham College, Basinghall-street, London, E.C.

Glasgow and West of Scotland Technical College.—The diploma of the college is granted in the departments of civil, electrical and mechanical engineering, mining, naval architecture, chemistry, metallurgy, mathematics and physics, building and textile manufactures. The courses of study usually extend over three sessions, and holders of the diploma are eligible for the degree of B.Sc. in engineering of the University of Glasgow, after attendance for at least one session at prescribed university classes. The laboratories are well equipped, and facilities for research are afforded in the departments of physics, electrical engineering, chemistry, metallurgy, mechanics, &c. The preliminary examination begins on Sept. 18, and names of candidates must be sent in by Sept. 1. The day classes begin Sept. 26 and the evening classes Sept. 21. Calendar (by post 1s. 4d.) and prospectuses (gratis) will be sent on application to the Director.

The calendar for the 116th session (1911-2) has just been issued, and shows how complete are the arrangements made for day and evening instruction at this college. There are full courses in mathematics, natural philosophy, the principles of engineering, chemistry, and various science and commercial subjects, &c. The calendar gives particulars of fees, bursaries and scholarships, examinations, &c., as well as interesting information regarding the history and development of the college, which has done much for technical education in Scotland.

City of Bradford Technical College.—At this college there are full day courses qualifying for the college diploma in civil, mechanical and electrical engineering. The next session commences Sept. 18. The new power house, especially arranged for experimental and educational work, will be opened during the session, and the equipment of the electrical engineering laboratories and machine room has also been considerably extended and brought up to date. Calendar, containing particulars of all courses, on application to the director of education, Mr. A. C. Coffin.

Northampton Polytechnic Institute, Clerkenwell, London.—The full day courses in the theory and practice of mechanical and electrical engineering, and in electro-chemistry will commence on Oct. 2, and entrance examinations will take place on Sept. 27 and 28, at which five entrance scholarships will be offered. The courses for mechanical and electrical engineering include periods spent in commercial workshops, and extend over four years, and they also prepare for the degree of B.Sc. in engineering of the University of London. There are also full and partial day courses in technical optics. Particulars from the Principal, Dr. R. Mullineux Walmsley.

South-Western Polytechnic Institute.—This institute provides a complete three-years' course, leading to a diploma or university degree, in electrical engineering. A four-years' course is held in the evening. Separate courses of lectures and practical work are given in elementary, intermediate and advanced electrical engineering, electrical design, a.c. and polyphase currents, wiring and fitting, &c. Particulars from the Secretary, Manresa-road, Chelsea, S.W.

Goldsmith's College (University of London).—At this college complete evening courses of instruction are provided in mechanical, electrical and constructional engineering, land surveying, fitting and machining, pattern-making and smithing. Students are prepared for the London University degree of B.Sc. in engineering, for the examinations of the Institution of Civil Engineers, Board of Education, and City and Guilds of London Institute, &c. Particulars from the Warden of the College, New Cross, S.E. The new session commences on Monday, Sept. 25, and enrolling will begin on the 18th inst.

Sunderland Municipal Technical College.—We have received a prospectus of the day classes at this college and also pamphlets giving particulars of the evening courses in electrical and mechanical engineering, naval architecture, building construction, mathematics and physics, chemistry, &c. The courses of instruction cover three years and prepare for the B.Sc. degree in engineering.

Merchant Venturers' Technical College, Bristol.—We have received a copy of the new calendar for this College, and note that the Faculty of Engineering of the University of Bristol (which is provided and maintained in the College) has arranged with the Institution of Civil Engineers for the recognition of the degrees in civil and mechanical engineering as exempting from the examinations of the Institution for its associateship, provided that the matriculation examination has been passed in the subjects prescribed by the Institution.

ARRANGEMENTS FOR THE WEEK.

BRITISH ASSOCIATION.

Friday, September 1st (To-day) to Tuesday, September 5th.
Meeting at Portsmouth.

THE LONDON ELECTRICAL ENGINEERS.

Officer Commanding, Col. H. M. Leaf.

The following orders have been issued :—
Head-quarters will be closed for instruction, but will be open for office work as under until further orders :—
Monday to Friday, 10 a.m. to 4 p.m.
Saturday, 10 a.m. to 12 noon.

Digitized by Google

GLASGOW CORPORATION ELECTRICITY SUPPLY ACCOUNTS.

Although the Glasgow Corporation electricity supply undertaking does not hand over for the relief of the rates large sums of money, as in the case of the Corporation's tramway undertaking (the accounts of which we analysed in our last issue), it is, nevertheless, in a prosperous condition, and is able to put aside a satisfactory sum to provide for depreciation. For the year ended May 31st last this contribution amounted to £44,552, or 0·26d. per unit, and the total amount set aside for this purpose during the last 10 years is no less than £393,821.

From our analysis below of the last year's expenditure it will be seen that several economies have been effected, as will also be gathered from the fact that, whilst the revenue has increased by £14,566, compared with last year's figure, the working expenses, including management and distribution costs, have only risen by £4,109. The excellence of this record will be appreciated when it is known that the number of units generated increased by 5,826,409. It will be noticed that the total cost per unit sold is now 1·23d., as against 1·33d. a year ago—that is, it has been reduced by $\frac{1}{10}$d.

Little need be said about the individual items in the cost set out below, but we should like to draw attention to the amount of rates and taxes. This was £22,198, or practically double the total cost of management; the charge of 0·13d. per unit sold is obviously a serious handicap on the undertaking, and under these circumstances it is very gratifying to notice that it has been found possible to supply no less than 7,021,142 units at ½d. per unit.

The total output during the 12 months under consideration was 40,823,090 units. Of this, 1,565,895 units were employed for public lighting, 193,655 units were sold by contract, and 39,063,540 units were sold to private consumers—an increase of 4,320,687 units. These 39,063,540 units were sold at the following prices :—

Lighting—			
Shops, warehouses, offices, theatres, halls, &c.		7,939,094 at	3½d.
" " " " "		3,822,279 at	¾d.
Domestic consumers, churches and public schools..		1,777,151 at	3d.
Special lighting		1,674,260 at	1½d.
" "		40,435 at	2d.
" "		382 at	1d.
		15,253,601	
Power and heating	6,206,398	at	1½d.
" "	9,172,412	at	¾d.
" "	1,409,987	at	1d.
" "	7,021,142	at	½d.
	23,809,939		
	39,063,540		

The following analysis of private consumers' accounts for the past year should prove of interest, particularly in connection with the figures for the number of consumers of each class a year ago. These latter figures are given in brackets :—

	No.		Consumption Units.
Consumers under 1 hour of max. demand	3,716	(3,537) ...	778,538
" " 2 hours " "	2,962	(2,919) ...	2,504,041
" " 3 " " "	1,661	(1,545) ...	2,187,929
" " 4 " " "	791	(695) ...	1,476,868
" " 5 " " "	348	(305) ...	1,203,799
" over 5 " " "	396	(375) ...	2,484,040
Theatres, halls and schools	308	(289) ...	1,246,228
Special	124	(102) ...	1,714,695
Domestic consumers and churches	6,895	(6,417) ...	1,657,463
Power	2,936	(2,630) ...	23,523,863
Heating	583	(340) ...	286,076
	20,720	(19,154)	39,063,540

It will be noticed that a considerable increase is shown in the number of consumers employing electricity for heating purposes. This is probably due to the scheme, which came into operation in October last, whereby domestic consumers can obtain a supply of energy for cooking, heating, &c., at 1d. per unit without separate wiring. The Electricity Committee state that this scheme has been adopted with favourable results. The number of consumers already benefiting by this scheme is 300.

The total number of consumers at May 31, 1911, was 21,166, compared with 19,489 at May 31, 1910, an increase of 1,677 consumers, or 8·6 per cent. during the year. More consumers have indeed been connected than for several years past.

As to the power load, 5,375 motors, of a total horse-power of 36,831, are now connected to the mains, 524 of these motors having been connected during the past 12 months.

The maximum demand upon the generating stations last winter amounted to 23,524 kw., compared with 21,719 kw. in the previous year, the corresponding load factors being 19·8 and 19·2 per cent. respectively. The Electricity Committee mention in their annual report that the fuel account shows that the use made of apparatus for ensuring the efficient and economical combustion of fuel has been fully justified. For the year 1909-10, 4·15 lb. of coal were used per unit generated; this year the figure is 3·47 lb., which represents a saving equivalent to 14,910 tons.

49,071,933 units were generated, 2,314,116 units being used on the works, and 5,934,727, or 12·1 per cent., being expended in distribution or otherwise not accounted for. Of the above total output, 32,356,818 units were generated at Port Dundas station, which transmits power at extra high pressure to all sub-stations as well as to Pollokshaws-road generating station. This latter station generated 16,162,267 units, Kelvinside station supplying the remaining 552,848 units.

We give below an analysis of the expenditure and revenue during the year ended May 31, 1911, together with the cost per unit sold of each item, the latter figures being also given for the preceding year :—

		Per unit sold. 1910-11.	1909-10.
Generating Costs.			
Fuel	£32,512	... 0·19d.	... 0·21d.
Oil, waste, water, &c.	2,333	... 0·01d.	... 0·02d.
Salaries and wages at station	14,900	... 0·09d.	... 0·10d.
Repairs and maintenance	9,511	... 0·06d.	... 0·05d.
Total Generating Costs	£59,256	0·35d.	0·38d.
Distribution Costs.			
Wages	£3,422	... 0·02d.	... 0·02d.
Repairs and maintenance of cables, &c.	5,469	... 0·03d.	... 0·03d.
Repairs and maintenance of meters, &c.	4,038	... 0·02d.	... 0·02d.
Total Distribution Costs	£12,929	0·07d.	0·07d.
Management Costs.			
Salaries	£6,471	... 0·04d.	... 0·04d.
Stationery, printing, &c.	1,200	... 0·01d.	... 0·01d.
General establishment charges	3,821	... 0·02d.	... 0·03d.
Total Management Costs	£11,492	0·07d.	0·08d.
Rents, rates and taxes	£22,198	... 0·13d.	... 0·14d.
Attending and repairing public and private lamps	£3,672	... 0·02d.	... 0·02d.
TOTAL COSTS (*ex.* capital charges)	**£109,547**	**... 0·64d.**	**... 0·69d.**
Capital Charges.			
Interest	£58,605	... 0·35d.	... 0·38d.
Sinking fund	41,142	... 0·24d.	... 0·26d.
Total Capital Charges	£99,747	0·59d.	0·64d.
TOTAL COSTS (*inc.* capital charges)	**£209,294**	**... 1·23d.**	**... 1·33d.**
Provision for depreciation	£44,552	... 0·26d.	... 0·28d.
Revenue.			
Sale of current per meter	£248,764	... 1·46d.	... 1·54d.
Public lighting	11,752	... 0·07d.	... 0·08d.
Rents of property	10	... 0·00d.	... 0·00d.
TOTAL REVENUE	**£260,526**	**1·53d.**	**1·62d.**
Balance	£6,680	... 0·04d.	... 0·01d.

This balance is placed to the credit of the reserve fund, which at May 31, 1911, stood at £27,468.

During the past year the capital expenditure amounted to £80,833, and the total capital expenditure at May 31, 1911, less depreciation written off, stood at £1,889,715.

SIR WM. RAMSAY'S ADDRESS TO THE BRITISH ASSOCIATION.*

The world has greatly changed since 1831, the year in which the British Association was founded; the spread of railways and the equipment of numerous lines of steamships have contributed to the peopling of countries at that time practically uninhabited. Moreover, not merely has travelling been made almost infinitely easier, but communication by post has been enormously expedited and cheapened; and the telegraph, the telephone and wireless telegraphy have simplified as well as complicated human existence. Furthermore, the art of engineering has made such strides that the question "Can it be done?" hardly arises, but rather "Will it pay to do it?" In a word, the human race has been familiarised with the applications of science; and men are ready to believe almost anything, if brought forward in its name.

Education, too, in the rudiments of science has been introduced into almost all schools; young children are taught the elements of physics and chemistry. The institution of a Section for Education in our Association (L) has had for its object the organising of such instruction, and much useful advice has been proffered. The problem is, indeed, largely an educational one; it is being solved abroad in various ways—in Germany and in most European States by elaborate Governmental schemes dealing with elementary and advanced instruction, literary, scientific and technical; and in the United States and in Canada by the farsightedness of the people: both employers and employés recognise the value of training and of originality, and on both sides sacrifices are made to ensure efficiency.

In England we have made technical education a local, not an Imperial question; instead of half-a-dozen first-rate institutions of University rank, we have a hundred in which the institutions are necessarily understaffed, in which the staffs are mostly overworked and underpaid; and the training given is that not for captains of industry but for workmen and foremen. "Efficient captains cannot be replaced by a large number of fairly good corporals." Moreover, to induce scholars to enter these institutions, they are bribed by scholarships, a form of pauperisation practically unknown in every country but our own; and to crown the edifice, we test results by examinations of a kind not adapted to gauge originality and character (if, indeed, these can ever be tested by examination), instead of, as on the Continent and in America, trusting the teachers to form an honest estimate of the capacity and ability of each student, and awarding honours accordingly.

The remedy lies in our own hands. Let me suggest that we exact from all gainers of University scholarships an undertaking that, if and when circumstances permit, they will repay the sum which they have received as a scholarship, bursary or fellowship. It would then be possible for an insurance company to advance a sum representing the capital value—viz., £7,464,931—of the scholarships, reserving, say, 20 per cent. for non-payment, the result of mishap or death. In this way a sum of over six million pounds, of which the interest is now expended on scholarships, would be available for University purposes. This is about one-fourth of the sum of 24 millions stated by Sir Norman Lockyer at the Southport meeting as necessary to place our university education on a satisfactory basis. A large part of the income of this sum should be spent in increasing the emoluments of the chairs; for, unless the income of a professor is made in some degree commensurate with the earnings of a professional man who has succeeded in his profession, it is idle to suppose that the best brains will be attracted to the teaching profession. And it follows that unless the teachers occupy the first rank, the pupils will not be stimulated as they ought to be.

Again, having made the profession of a teacher so lucrative as to tempt the best intellects in the country to enter it, it is clear that such men are alone capable of testing their pupils. The modern system of "external examinations," known only in this country, and answerable for much of its lethargy, would disappear; schools of thought would arise in all subjects, and the intellectual as well as the industrial prosperity of our nation would be assured. As things are, can we wonder that as a nation we are not scientific? Let me recommend those of my hearers who are interested in the matter to read a recent report on technical education by the Science Guild.

I venture to think that, in spite of the remarkable progress of science and of its applications, there never was a time when missionary effort was more needed. Although most people have some knowledge of the results of scientific inquiry, few, very few, have entered into its spirit. We all live in hope that the world will grow better as the years roll on. Are we taking steps to secure the improvement of the race? I plead for recognition of the fact that progress in science does not only consist in accumulating information which may be put to practical use, but in developing a spirit of prevision, in taking thought for the morrow; in attempting to forecast the future, not by vague surmise, but by orderly marshalling of facts, and by deducing from them their logical outcome; and chiefly in endeavouring to control conditions which may be utilised for the lasting good of our people. We must cultivate a belief in the "application of trained intelligence to all forms of national activity."

The question has often been debated whether the present method of conducting our proceedings is the one best adapted to gain our ends. We exist professedly "to give a stronger impulse and a more systematic direction to scientific inquiry." The Council has had under consideration various plans framed with the object of facilitating our work, and the result of its deliberations will be brought under your attention at a later date. To my mind, the greatest benefit bestowed on science by our meetings is the opportunity which they offer for friendly and unrestrained intercourse, not merely between those following different branches of science, but also with persons, who, though not following science professionally, are interested in its problems. Our meetings also afford an opportunity for younger men to make the acquaintance of older men. I am afraid that we, who are no longer in the spring of our lifetime, perhaps from modesty, perhaps through carelessness, often do not sufficiently realise how stimulating to a young worker a little sympathy can be; a few words of encouragement go a long way. I have in my mind words which encouraged me as a young man, words spoken by the leaders of Associations, now long past—by Playfair, by Williamson, by Frankland, by Kelvin, by Stokes, by Francis Galton, by Fitzgerald and many others. Let me suggest to my older scientific colleagues that they should not let such pleasant opportunities slip.

After referring by name to distinguished members of the Association who had died since the last address was delivered, the President proceeded to give an account of ancient and modern views regarding the chemical elements. He dealt with the theories held by the Greeks, by Boyle, by Stahl and his phlogiston theory, by Lavoiser, Dalton and Davy. Indeed, in those days the ancient idea of the unitary nature of matter was held to be highly probable, and much work on this hypothesis was done by Liebeg, Redtenbacher, Dunn, Döbereiner and Newlands, and at a later date by Meyer and Mendeléeff. By this time it might have been supposed that our knowledge of the elements was practically complete, but the discovery of radio-activity by Becquerel, and the work of the Curies, Rutherford and Soddy have indicated the existence of no fewer than 26 elements hitherto unknown, and of these radium is found to be unstable. Now, stability was believed to be the essential characteristic of an element. Radium disintegrates and gives off radium emanation and helium. The former in its turn disintegrates much more rapidly than radium, with the evolution of helium, and what is left goes through a series of changes until it finally becomes radium F or polonium, which itself disintegrates into an unknown metal, possibly lead.

For the first time we have accurate knowledge as to the descent of some of the elements. Supposing the atomic weight of uranium to be certainly 239, it may be taken as proved that in losing three atoms of helium, radium is produced, and, if the change consists solely in the loss of the three atoms of helium, the atomic weight of radium must necessarily be 227. But it is known that β-rays, or electrons, are also parted with during this change; and electrons have weight. How many electrons are lost is unknown; therefore, although the weight of an electron is approximately known, it is impossible to say how much to allow for in estimating the atomic weight of radium. But it is possible to solve this question indirectly by determining exactly the atomic weights of radium and of uranium; the difference between the atomic weight of radium *plus* 12, *i.e.*, plus the weight of three atoms of helium, and that of uranium, will give the weight of the number of electrons which escape. Taking the most probable numbers available—viz., 239·4 for uranium and 226·8 for radium—and adding 12 to the latter, the weight of the escaping electrons would be 0·6.

The correct solution of this problem would in great measure clear up the mystery of the irregularities in the periodic table, and would account for the deviations from Prout's Law, that the atomic weights are multiples of some common factor or factors. I also venture to suggest that it would throw light on allotropy, which in some cases at least may very well be due to the loss or gain of electrons, accompanied by a positive or negative heat-change. Incidentally, this suggestion would afford places in the periodic table for the somewhat overwhelming number of pseudo-elements, the existence of which is made practically certain by the disintegration hypothesis. Of the 26 elements derived from uranium, thorium and actinium, 10, which are formed by the emission of electrons alone, may be regarded as allotropes or pseudo-elements; this leaves 16, for which 16 or 17

* Abstract of the Presidential Address delivered by Prof. Sir William Ramsay, K.C.B., D.Sc., F.R.S., to the British Association on Wednesday last.

Digitized by Google

gaps would appear to be available in the periodic table, provided the reasonable supposition be made that a second change in the length of the periods has taken place. It is above all things certain that it would be a fatal mistake to regard the existence of such elements as irreconcilable with the periodic arrangement, which has rendered to systematic chemistry such signal service in the past.

Attention has repeatedly been drawn to the enormous quantity of energy stored up in radium and its descendants. That in its emanation, niton, is such that if what it parts with as heat during its disintegration were available, it would be equal to three and a half million times the energy available by the explosion of an equal volume of detonating gas—a mixture of one volume of oxygen with two volumes of hydrogen. The major part of this energy comes, apparently, from the expulsion of particles (that is, of atoms of helium) with enormous velocity. It is easy to convey an idea of this magnitude in a form more realisable by giving it a mechanical turn. Suppose that the energy in a ton of radium could be utilised in 30 years, instead of being evolved at its invariable slow rate of 1,760 years for half-disintegration, it would suffice to propel a ship of 15,000 tons, with engines of 15,000 H.P., at the rate of 15 knots, for 30 years—practically the *lifetime* of the ship. To do this actually requires a million and a half tons of coal.

It is easily seen that the virtue of the energy of the radium consists in the small weight in which it is contained; in other words, the radium-energy is in an enormously concentrated form. I have attempted to apply the energy contained in niton to various purposes; it decomposes water, ammonia, hydrogen chloride and carbon dioxide, each into its constituents; further experiments on its action on salts of copper appeared to show that the metal copper was converted partially into lithium, a metal of the sodium column; and similar experiments, of which there is not time to speak, indicate that thorium, zirconium, titanium and silicon are degraded into carbon; for solutions of compounds of these, mixed with niton, invariably generated carbon dioxide; while cerium, silver, mercury and some other metals gave none. One can imagine the very atoms themselves, exposed to bombardment by enormously quickly moving helium atoms, failing to withstand the impacts. Indeed, the argument *a priori* is a strong one; if we know for certain that radium and its descendants decompose spontaneously, evolving energy, why should not other more stable elements decompose when subjected to enormous strains?

This leads to the speculation whether, if elements are capable of disintegration, the world may not have at its disposal a hitherto unsuspected source of energy. If radium were to evolve its stored-up energy at the same rate that gun-cotton does, we should have an undreamt-of explosive; could we control the rate we should have a useful and potent source of energy, provided always that a sufficient supply of radium were forthcoming. But the supply is certainly a very limited one; and it can be safely affirmed that the production will never surpass half-an-ounce a year. If, however, the elements which we have been used to consider as permanent are capable of changing with evolution of energy; if some form of catalyser could be discovered which would usefully increase their almost inconceivably slow rate of change, then it is not too much to say that the whole nature of our race would be altered.

The whole progress of the human race has indeed been due to individual members discovering means of concentrating energy, and transforming one form into another. Great progress has been made during the past century in effecting the conversion of one form of energy into others, with as little useless expenditure as possible. The middle of the nineteenth century will always be noted as the beginning of the golden age of science; the epoch when great generalisations were made, of the highest importance on all sides, philosophical, economic and scientific. Carnot, Clausius, Helmholtz, Julius Robert Mayer abroad, and the Thomsons, Lord Kelvin and his brother James, Rankine, Tait, Joule, Clerk Maxwell and many others at home, laid the foundations on which the splendid structure has been erected. That the latent energy of fuel can be converted into energy of motion by means of the steam engine is what we owe to Newcomen and Watt; that the kinetic energy of the flywheel can be transformed into electrical energy was due to Faraday, and to him, we are indebted for the re-conversion of electrical energy into mechanical work; and it is this power of work which gives us leisure, which enables a small country like ours to support the population which inhabits it.

We have in this world of ours only a limited supply of stored-up energy; in the British Isles a very limited one—namely, our coal-supply. The rate at which this supply is being exhausted has been increasing very steadily for the last 40 years, as anyone can prove by plotting the data given on p. 27, table D, of the General Report of the Royal Commission on Coal Supplies (1906). In 1870 110 million tons were mined in Great Britain, and ever since the amount has increased by three and a third million tons a year. The available quantity of coal in the proved coalfields is very nearly 100,000 million tons; it is easy to calculate that if the rate of working increases as it is doing, our coal will be completely exhausted in 175 years. But, it will be replied, the rate of increase will slow down. Why? It has shown no sign whatever of slackening during the last 40 years. Later, of course, it must slow down, when coal grows dearer owing to approaching exhaustion.

This consumption is still proceeding at an accelerated rate. Between 1905 and 1907 the amount of coal raised in the United Kingdom increased from 236 to 268 million tons, equal to six tons per head of the population, against 3½ tons in Belgium, 2½ tons in Germany and 1 ton in France. Our commercial supremacy and our power of competing with other European nations are obviously governed, so so far as we can see, by the relative price of coal; and when our prices rise, owing to the approaching exhaustion of our supplies, we may look forward to the near approach of famine and misery.

Having been struck some years ago with the optimism of my non-scientific friends as regards our future, I suggested that a committee of the British Science Guild should be formed to investigate our available sources of energy. The Science Guild has enlisted the services of a number of men, each eminent in his own department, and each has now reported on the particular source of energy of which he has special knowledge. Besides concerning the uses of coal and its products, and how they may be more economically employed, in which branches the Hon. Sir Charles Parsons, Mr. Dugald Clerk, Sir Boverton Redwood, Dr. Beilby, Dr. Hele-Shaw, Prof. Vivian Lewes and others have furnished reports, the following sources of energy have been brought under review: The possibility of utilising the tides; the internal heat of the earth; the winds; solar heat; water-power; the extension of forests, and the use of wood and peat as fuels; and, lastly, the possibility of controlling the undoubted but almost infinitely slow disintegration of the elements, with the view of utilising their stored-up energy.

However interesting a detailed discussion of these possible sources of energy might be, time prevents my dwelling on them. Suffice it to say that the Hon. R. J. Strutt has shown that in this country at least it would be impracticable to attempt to utilise terrestrial heat from bore-holes; others have deduced that from the tides, the winds and water-power small supplies of energy are no doubt obtainable, but that, in comparison with that derived from the combustion of coal, they are negligible; nothing is to be hoped for from the direct utilisation of solar heat in this temperate and uncertain climate; and it would be folly to consider seriously a possible supply of energy in a conceivable acceleration of the liberation of energy by atomic change. It looks utterly improbable, too, that we shall ever be able to utilise the energy due to the revolution of the earth on her axis, or to her proper motion round the sun.

Attention should undoubtedly be paid to forestry, and to the utilisation of our stores of peat. On the Continent, the forests are largely the property of the State; it is unreasonable, especially in these latter days of uncertain tenure of property, to expect any private owner of land to invest money in schemes which would at best only benefit his descendants, but which, under our present trend of legislation, do not promise even that remote return. Our neighbours and rivals, Germany and France, spend annually £2,200,000 on the conservation and utilisation of their forests; the net return is £6,000,000. There is no doubt that we could imitate them with advantage. Moreover, an increase in our forests would bring with it an increase in our water-power; for without forest land rain rapidly reaches the sea, instead of distributing itself, so as to keep the supply of water regular, and so more easily utilised. Various schemes have been proposed for utilising our deposits of peat: I believe that in Germany the peat industry is moderately profitable; but our humid climate does not lend itself to natural evaporation of most of the large amount of water contained in peat, without which processes of distillation prove barely remunerative.

We must therefore rely chiefly on our coal reserve for our supply of energy, and for the means of supporting our population; and it is to the more economical use of coal that we must look, in order that our life as a nation may be prolonged. We can economise in many ways: By the substitution of turbine engines for reciprocating engines, thereby reducing the coal required per horse-power from 4 lb. to 5 lb. to 1½ lb. or 2 lb.; by the further replacement of turbines by gas engines, raising the economy to 30 per cent. of the total energy available in the coal—that is, lowering the coal consumption per horse-power to 1 lb. or 1¼ lb.; by creating the power at the pit-mouth, and distributing it electrically, as is already done in the Tyne district. Economy can also be effected in replacing "beehive" coke ovens by recovery ovens; this is rapidly being done; and Dr. Beilby calculates that in 1909 nearly six million tons of coal, out of a total of 16 to 18 millions, were coked in recovery ovens, thus effecting

Digitized by Google

a saving of two to three million tons of fuel annually. Progress is also being made in substituting gas for coal or coke in metallurgical, chemical, and other works. But it must be remembered that for economic use, gaseous fuel must not be charged with the heavy costs of piping and distribution.

The domestic fire problem is also one which claims our instant attention. It is best grappled with from the point of view of smoke. Although the actual loss of thermal energy in the form of smoke is small—at most less than ½ per cent. of the fuel consumed—still the presence of smoke is a sign of waste of fuel and careless stoking. In works, mechanical stokers which ensure regularity of firing and complete combustion of fuel are more and more widely replacing hand-firing. But we are still utterly wasteful in our consumption of fuel in domestic fires. There is probably no single remedy applicable; but the introduction of central heating, of gas fires, and of grates which permit of better utilisation of fuel will all play a part in economising our coal. It is open to argument whether it might not be wise to hasten the time when smoke is no more by imposing a sixpenny fine for each offence; an instantaneous photograph could easily prove the offence to have been committed; and the imposition of the fine might be delayed until three warnings had been given by the police.

Now, I think that what I wish to convey will be best expressed by an allegory. A man of mature years who has surmounted the troubles of childhood and adolescence without much disturbance to his physical and mental state gradually becomes aware that he is suffering from loss of blood; his system is being drained of this essential to life and strength. What does he do? If he is sensible, he calls in a doctor, or perhaps several, in consultation; they ascertain the state of the disease, and diagnose the cause. They point out that while consumption of blood is necessary for healthy life, it will lead to a premature end if the constantly increasing drain is not stopped. They suggest certain precautionary measures; and if he adopts them, he has a good chance of living at least as long as his contemporaries; if he neglects them, his days are numbered. That is our condition as a nation. We have had our consultation in 1903; the doctors were the members of the Coal Commission. They showed the gravity of our case, but we have turned a deaf ear.

It is true that the self-interest of coal consumers is slowly leading them to adopt more economical means of turning coal into energy. But I have noticed and frequently publicly announced a fact which cannot but strike even the most unobservant. It is this: When trade is good, as it appears to be at present, manufacturers are making money; they are overwhelmed with orders, and have no inclination to adopt economies which do not appear to them to be essential, and the introduction of which would take thought and time, and which would withdraw the attention of their employés from the chief object of the business—how to make the most of the present opportunities. Hence improvements are postponed. When bad times come, then there is no money to spend on improvements; they are again postponed until better times arrive. What can be done? I would answer: Do as other nations have done and are doing; take stock annually. The Americans have a permanent Commission, initiated by Mr. Roosevelt, consisting of three representatives from each State, the sole object of which is to keep abreast with the diminution of the stores of natural energy, and to take steps to lessen its rate. This is a non-political undertaking, and one worthy of being initiated by the ruler of a great country. If the example is followed here the question will become a national one.

Two courses are open to us; first, the *laissez-faire* plan of leaving to self-interested competition the combating of waste; or, second, initiating legislation which, in the interest of the whole nation, will endeavour to lessen the squandering of our national resources. This legislation may be of two kinds: penal, that is, imposing a penalty on wasteful expenditure of energy-supplies; and helpful, that is, imparting information as to what can be done, advancing loans at an easy rate of interest to enable reforms to be carried out, and insisting on the greater prosperity which would result from the use of more efficient appliances.

This is not the place, nor is there the time, to enter into detail; the subject is a complicated one, and it will demand the combined efforts of experts and legislators for a generation; but if it be not considered with the definite intention of immediate action, we shall be held up to the deserved execration of our not very remote descendants.

The two great principles which I have alluded to in an earlier part of this address must not, however, be lost sight of; they should guide all our efforts to use energy economically. Concentration of energy in the form of electric current at high potential makes it possible to convey it for long distances through thin and therefore comparatively inexpensive wires; and the economic coefficient of the conversion of mechanical into electrical, and of electrical into mechanical energy is a high one; the useless expenditure does not much exceed one-twentieth part of the energy which can be utilised. These considerations would point to the conversion at the pit-mouth of the energy of the fuel into electrical energy, using as an intermediary, turbines, or preferably gas engines; and distributing the electrical energy to where it is wanted. The use of gas engines may, if desired, be accompanied by the production of half-distilled coal, a fuel which burns nearly without smoke, and one which is suitable for domestic fires, if it is found too difficult to displace them and to induce our population to adopt the more efficient and economical systems of domestic heating which are used in America and on the Continent. The increasing use of gas for factory, metallurgical and chemical purposes points to the gradual concentration of works near the coal mines, in order that the laying-down of expensive piping may be avoided.

An invention which would enable us to convert the energy of coal directly into electrical energy would revolutionise our ideas and methods, yet it is not unthinkable. The nearest practical approach to this is the Mond gas-battery, which, however, has not succeeded, owing to the imperfection of the machine.

In conclusion, I would put in a plea for the study of pure science, without regard to its applications. The discovery of radium and similar radio-active substances has widened the bounds of thought. While themselves, in all probability, incapable of industrial application, save in the domain of medicine, their study has shown us to what enormous advances in the concentration of energy it is permissible to look forward, with the hope of applying the knowledge thereby gained to the betterment of the whole human race. As charity begins at home, however, and as I am speaking to the *British* Association for the Advancement of Science, I would urge that our first duty is to strive for all which makes for the permanence of the British Commonweal, and which will enable us to transmit to our posterity a heritage not unworthy to be added to that which we have received from those who have gone before.

AMERICAN STANDARD TABLES FOR BARE COPPER CABLES.*

The appended tables give data on bare concentric cables of standard annealed copper. A "concentric cable" is a conductor made up of a straight central wire surrounded by one or more layers of wires, the alternate layers having a twist in opposite directions. In the first layer about the central wire, six wires of the same diameter are used; in the next layer 12, then 18, 24, &c. The number of layers thus determines the number of individual wires in the cable. There are many other more complicated forms of cables, but these are not considered here. The size of the individual wires or "strands"† may be taken to be a definite gauge number, but it is the more usual practice to start with a specified total cross-section for the cable and from that calculate the diameter of the strands. In these tables, the column "diameter of wires" was calculated from the total cross-section.

The various sizes of cables are designated in commercial practice by a statement of the total cross-section in "circular mils" (the cross-section in circular mils of a single wire is the square of its diameter in mils). It is believed that these tables contain the more usual sizes which are made and used in the United States. The practices of manufacturers vary, and the "number of wires" given in the table for each value of "circular mils" may not represent the practices of all manufacturers. For some purposes a more flexible cable is wanted than in other cases, and this end is attained by using finer wire and increasing the number of layers and of wires. The list of sizes and "number of wires" used in these tables are those given as representing average American practice in a report by Mr. H. W. Fisher to the Standards Committee of the American Institute of Electrical Engineers, in January, 1911. Accordingly these tables do not present an arbitrary set of data on cables, especially since it will be shown below that the table involves no selection of values for the "lay" or pitch.

* We are enabled to publish these tables, &c., by the courtesy of Dr. S. W. Stratton, Director of the Bureau of Standards, Washington.

† A "strand" is any component part of a cable. In the case of a concentric cable, therefore, the meaning of the term is definitely limited to the individual wire of the cable.

Digitized by Google

The "outside diameter in mils" or "outside diameter in millimetres" is the diameter of the circle circumscribing the cable, and is calculated very simply. Thus, for a cable of seven wires the "outside diameter" is three times the diameter of one wire; for a cable of 19 wires it is five times the diameter of one wire, &c. The values given for the resistance are based on the "annealed copper standard,"* an average for the present-day copper used in electrical work, determined by the Bureau of Standards, and accepted by the American Institute of Electrical Engineers. The density used in calculating the mass is 8·89 grammes per cubic centimetre, or 0·32117 lb. per cubic inch. The effect of the twisting of the strands on the resistance and mass per unit length is discussed in the following paragraphs.

Different authors and different cable companies do not agree in their methods of calculating the resistance of cables. It is usually stated that on account of the stranding the lengths of the individual wires are increased, and hence the resistance of the cable is *greater* than the resistance of an "equivalent solid rod"—*i.e.*, a solid wire or rod of the same length and of cross-section equal to the total cross-section of the cable (taking the cross-section of each wire perpendicular to the axis of the wire). However, there is always some contact area between the wires of a cable, which has the effect of increasing the cross-section and decreasing the resistance; and some authors have gone so far as to state that the resistance of a cable is *less* than that of the equivalent solid rod. The Bureau of Standards has made inquiries to ascertain the experience of cable manufacturers and others on this point. It is practically unanimously agreed that the resistance of a cable is actually *greater* than the resistance of an equivalent solid rod. It is shown mathematically in the appendix below that the percentage increase of resistance of a cable with all the wires perfectly insulated from one another, over the resistance of the equivalent solid rod, is exactly equal to the percentage decrease of resistance of a cable in which each strand makes perfect contact with a neighbouring strand at all points of its surface. That is, the resistance of the equivalent solid rod is the arithmetical mean of these two extreme cases. Since the resistance of the cable must necessarily lie between these two extremes, the resistance of the equivalent solid rod is not greatly different from the resistance of the actual cable; the difference must be less than the difference between the mean and either extreme.

Accordingly, in the tables the values of "ohms per 1,000 ft." and "ohms per kilometre" are calculated for a solid wire or rod of the same length and total cross-section as the cable. As stated above, experience has shown that the actual resistance of a cable is greater than this. This is due, no doubt, to the fact that the wires are not distorted much from their circular shape, and hence are very far from making perfect contact with each other. But the actual departure of the resistance of a cable from these tabulated values depends further upon the "lay" or "pitch" on the tension under which the strands are wound, the age of the cable, the variations of the resistivity of the wires, variations of temperature, &c., so that it is very doubtful whether any correction should ever be made to the tabulated values.

The actual *mass* per unit length of a cable cannot be calculated without a knowledge of the pitch or lay; and this varies greatly for different sizes of cable and different manufacturers. Although unsatisfactory it is therefore necessary to calculate "pounds per 1,000 ft." and "kilogrammes per kilometre" on the assumption that the wires of the cable are not twisted—*i.e.*, that the mass of the cable is the same as the mass of the "equivalent solid rod" of the same length and total cross-section. In actual use, therefore, a correction must be *added* to the values in the tables, the amount of the correction depending on the amount of twist. The correction is smaller the more gradual the twist. The effect of "lay" and the magnitude of the correction are discussed in the following appendix.

* THE ELECTRICIAN, Vol. LXVI., p. 906, March 17, 1911. "Bulletin" of the Bureau of Standards, VII., p. 103, 1910.

NOTE 1.—The *fundamental resistivity* used in calculating the table is the annealed copper standard—viz., 0·153022 ohm per metre-gramme at 20°C. The *temperature coefficient* for this particular resistivity is $\alpha_{20}=0{\cdot}00394$, or $\alpha_0=0{\cdot}00423$. However, the temperature coefficient is proportional to the conductivity, and hence the change of *resistivity* per degree Centigrade is a constant, 0·000598 ohm per metre-gramme. The "constant mass" temperature coefficient of any sample is

$$\alpha_t = \frac{0{\cdot}000598 + 0{\cdot}000005}{\text{resistivity in ohms per metre-gramme at } t°\text{C.}}$$

The *density* is 8·89 grammes per cubic centimetre.

NOTE 2.—"Ohms per 1,000 ft." and "Pounds per 1,000 ft." are calculated for a solid rod of the same length and of cross-section equal to the total cross-section of the wires of the cable. The resistance of an actual cable is likely to be somewhat greater than the value given by the table, but not much greater. However, the *mass* per unit length of an actual cable is necessarily increased by the stranding, and hence a *correction must be added* whose amount depends on the "lay" of the cable. The value of the correction relative to the whole mass is $\left(\frac{4{\cdot}9}{n^2}\right)$, where the lay is "1 in n." For any lay more gradual than about 1 in 20, the correction is less than 1 per cent.

APPENDIX.

CALCULATION OF THE RESISTANCE AND MASS PER UNIT LENGTH OF CABLES.

In the first place, it is proposed to show that the percentage increase of resistance of a cable with all the wires perfectly insulated from one another over the resistance of the "equivalent solid rod" is exactly equal to the percentage decrease of

NOTES.—The fundamental resistivity, temperature coefficient and density are given in Note 1 of the preceding table. Note 2 explains the calculations of ohms per unit length and mass per unit length.

resistance of a cable in which each strand makes perfect contact with a neighbouring strand at all points of its surface. That is, if R_s = resistance of a solid wire or rod of the same length and of cross-section equal to the total cross-section of the cable (taking the cross-section of each wire perpendicular to the axis of the wire), R_1 = resistance of a cable with the individual wires perfectly insulated from one another, R_2 = resistance of a hypothetical cable with the wires distorted into such shape that they make perfect contact at all points of their surfaces (the layers all being twisted in the same direction), then

$$R_s = \frac{R_1 + R_2}{2}.$$

$R_1 > R_s$, because on account of the stranding the path of the current is longer than it would be if parallel to the axis of the cable. $R_2 < R_s$, because the path of the current is in this case parallel to the axis of the cable, which path has a greater cross-section than the sum of the cross-sections of each wire taken perpendicular to the axis of the wire.

$$\therefore R_1 > R_s > R_2.$$

In showing that R_s is just half-way between R_1 and R_2, we use the symbols :—

ρ = volume resistivity.

l = length along axis of cable, or length of "equivalent solid rod."

s = total cross-section of the wires of the cable, taken perpendicular to axis of wire, or cross-section of "equivalent solid rod."

$\triangle l$ = increase of length of strand due to twisting.

$\triangle s$ = increase of cross-section perpendicular to axis of cable due to twisting.

We have

$$R_s = \frac{\rho l}{s} \quad \ldots\ldots\ldots (1)$$

$$R_1 = \frac{\rho(l + \triangle l)}{s} \quad \ldots\ldots\ldots (2)$$

$$R_2 = \frac{\rho l}{s + \triangle s}. \quad \ldots\ldots\ldots (3)$$

The following diagram (Fig. 1) shows a side view of one strand of a cable. In the diagram only one dimension of the

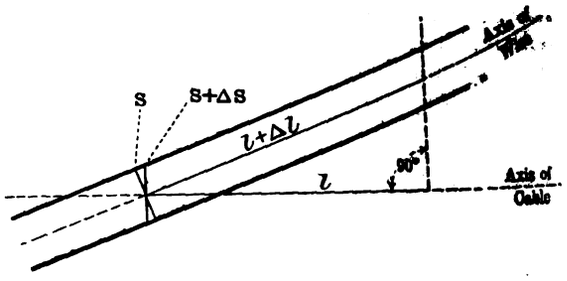

FIG. 1.

cross-section s is shown ; the dimension perpendicular to this is unchanged by the twisting, and hence s is proportional to the dimension shown.

By similar triangles,

$$\frac{s + \triangle s}{s} = \frac{l + \triangle l}{l},$$

$$s + \triangle s = s\left(1 + \frac{\triangle l}{l}\right). \quad \ldots\ldots (4)$$

$$\therefore R_2 = \frac{\rho l}{s\left(1 + \frac{\triangle l}{l}\right)} = \frac{\rho l}{s}\left(1 - \frac{\triangle l}{l}\right), \text{ since } \frac{\triangle l}{l} \text{ is small.} \quad (5)$$

From (2),

$$R_1 = \frac{\rho l}{s}\left(1 + \frac{\triangle l}{l}\right). \quad \ldots\ldots (6)$$

$$\therefore R_1 + R_2 = \frac{2\rho l}{s}. \quad \ldots\ldots\ldots (7)$$

From (1) and (7),

$$R_s = \frac{R_1 + R_2}{2}. \qquad \text{Q.E.D.}$$

The resistance of an actual cable must be between R_1 and R_2. Although the case represented by R_2 is highly hypothetical, still the effect of contact between the wires is not negligible. This is shown by the fact that the resistance of cables increases with age, which may be considered to be due to contamination of the wire surfaces. Hence, while the resistance of a cable may not exactly equal R_s, it is greater than R_s by an amount less than $(R_1 - R_s)$. By equations (1) and (6),

$$\frac{R_1 - R_s}{R_s} = \frac{\triangle l}{l}$$

The resistance of a cable is then greater than R_s by a fractional amount less than $\triangle l/l$.

The *mass* of a cable is greater than the mass of the "equivalent solid rod" by a fractional amount exactly equal to $\triangle l/l$. This is readily seen, and may be considered to be due either to increase of length or to increase of cross-section. Since the mass per unit length in the tables is calculated for the "equiva-

Digitized by Google

lent solid rod," they should strictly be corrected in use by the factor $(1+\Delta l/l)$. The method of computing this factor from the "lay" of the cable is given herewith.

Let d=diameter of the helical path of one strand.

L=length along axis of cable for one complete revolution of strand about axis.

$n=\frac{L}{d}$=number of times the diameter, d, is contained in the length L.

"Lay"=$d/L=1/n$=ratio of the diameter d to the length L. The lay is usually expressed as $1/n$ or "1 in n"; thus we may speak of a lay of 1/20, or 1 in 20.

Consider a strand of length $(L+\Delta L)$, developed in a plane containing the axis of the cable of length L. The developed

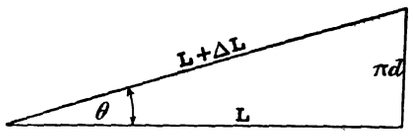

FIG. 2.

strand and the axis make with each other the angle θ, in Fig. 2. The third side of the triangle equals in length the circumference of the helical path of the strand.

$$\tan\theta=\frac{\pi d}{L}=\frac{\pi}{n}.$$

$$\frac{L+\Delta L}{L}=\sec\theta=\sqrt{1+\tan^2\theta},$$

$$=\sqrt{1+\frac{\pi^2}{n^2}}$$

$$=1+\frac{1}{2}\left(\frac{\pi^2}{n^2}\right)-\frac{1}{8}\left(\frac{\pi^2}{n^2}\right)^2+\ldots\ldots$$

All terms of higher order than the first are negligible for the purpose in hand, hence the correction factor to be applied to the tabulated values of mass per unit length is

$$\left(1+\frac{\Delta l}{l}\right)=\left(1+\frac{\Delta L}{L}\right)=1+\frac{1}{2}\left(\frac{\pi^2}{n^2}\right).$$

For example, if the lay is 1 in 40, $n=40$, and the correction factor is $(1+\frac{1}{2}\frac{9{\cdot}87}{1{,}600}=(1+0{\cdot}30$ per cent.).

If the lay is 1 in 20, the correction factor is (1+1·2 per cent).

If the lay is 1 in 10, the correction factor is (1+4·9 per cent.).

This correction factor must be computed separately for each layer of the strands when the lay is different for different layers of the cable. If L is the same for each layer of the cable the lay varies because of the change of d. It should not be forgotten that the central wire is untwisted.

Bureau of Standards, U.S.A., July 29, 1911.

THE FUNDAMENTAL PROPERTIES OF THE ELEMENTS.*

BY PROF. T. W. RICHARDS.

The mystery that enshrouds the ultimate nature of the physical universe has always stimulated the curiosity of thinking man. Of old, philosophers sought to solve the cosmic problem by abstract reasoning, but to-day we agree that the only hope of penetrating into the closely guarded secret lies in the precise estimation of that which is tangible and visible. Knowledge of the actual behaviour of material and of energy provides the only safe basis for logical inference as to the real essence of things. Faraday was deeply imbued with this conviction; and it is widely recognised as the basis of all modern experimental science. The subject of my lecture to-night concerns the methods and general results of several extended series of investigations, planned with the hope of adding a little to the foundations of human knowledge by means of careful experiment.

*Abstract of the Faraday Lecture delivered before the Chemical Society.

What, now, are the most important precautions to be taken in such work? These are worthy of brief notice, because the value of the results inevitably depends upon them. Obvious although they may be, they are often disregarded. In the first place, each portion of substance to be weighed must be free from the suspicion of containing unheeded impurities; otherwise its weight will mean little. This is an end not easily attained, for liquids often attack their containing vessels and absorb gases, crystals include and occlude solvents, precipitates carry down polluting impurities, dried substances cling to water, and solids, even at high temperatures, often fail to discharge their imprisoned contaminations. In the next place, after an analysis has once begun, every trace of each substance to be weighed must be collected and find its way in due course to the scale pan. The trouble here lies in the difficulty in estimating, or even detecting, minute traces of substances remaining in solution, or minute losses by vaporisation at high temperatures.

In brief, "the whole truth and nothing but the truth" is the aim. The chemical side of the question is far more intricate and uncertain than the physical operation of weighing. For this reason it is neither necessary nor advisable to use extraordinarily large amounts of material; from 5 to 20 grammes in each experiment is usually enough. The exclamation, "What wonderfully fine scales you must have to weigh atoms," simply indicates ignorance; the real difficulties precede the introduction of the substance into the balance case. Every substance must be assumed to be impure, every reaction must be assumed to be incomplete, every measurement must be assumed to contain error, until proof to the contrary can be obtained. Only by means of the utmost care, applied with ever-watchful judgment, may the unexpected snares which always lurk in complicated processes be detected and rendered powerless for evil. Among all the possibilities of error, the unsuspected presence of water is perhaps the most frequent and most insidious. The two errors—namely, the presence of residual water and the loss of traces of precipitate respectively—have perhaps ruined more previous investigations than any other two causes, unless the inclusion of foreign substances by precipitates may be ranked as an equal vitiating effect. But these are merely details; the scope and method of the recent work on this subject at Harvard (in the course of which 30 atomic weights have been re-determined) may be seen in their full bearing only in the original Papers.*

That the atomic weights may be connected by precise mathematical equations seems highly probable; but although many interesting attempts have been made to solve the problem, the exact nature of such relationships has not yet been discovered. No attempt which takes liberties with the more certain of the observed values is worthy of much respect. It seems to me that the discovery of the ultimate generalisation is not likely to occur until many atomic weights have been determined with the greatest accuracy. No trouble being too great to attain this end, the Harvard work will be continued indefinitely, and attempts will be made to improve its quality, for the discovery of an exact mathematical relationship between atomic weights would afford us an immeasurably precious insight into the ultimate nature of things.

But weight is only one of the fundamental properties of an element. Volume is almost, if not quite, as important in its own way, although far more variable and confusing. All gases, indeed, approach closely to a simple relationship of volumes, defined by the law of Gay Lussac and the rule of Avogadro. In the liquid and solid state, however, great irregularities are manifest, and very little system as regards volume is generally recognised.

About 12 years ago the study of such small irregularities as exist among gases led me to the suspicion of a possible cause for the greater irregularities in liquids and solids. The next step in the train of thought is perhaps equally obvious. If changes in the bulk of molecules are to be inferred even from gases, may not the expansion and contraction of solids and liquids afford a much better clue to the relative expansion and contraction of these molecules?

Most physical chemists refer all changes in volume to changes in the extent of the *empty space* between the molecules. But are there, after all, any such empty spaces in solids and liquids? Solids do not behave as if the atoms were far apart within them; porosity is often conspicuous by its absence. Take, for instance, the case of glass; the careful experiments of Landolt on the conservation of weight show that glass is highly impermeable to oxygen, nitrogen and water for long periods. Such porosity as occurs in rigid, com-

*An important part in these researches has been taken by G. P. Baxter, and many able students also have assisted the author in the work. A complete bibliography is given in "Publ. Carnegie Inst. of Washington," 1910, No. 125, 91. Most of the Papers are reprinted in full in a volume entitled "Experimentelle Untersuchungen über Atomgewichte," by the author and his collaborators (Hamburg, 1909). The Carnegie Institution of Washington has generously subsidised the work in recent years.

Digitized by Google

pact solids usually permits the passage only of substances which enter into the chemical structure of the solids themselves. In these cases, as in so many others, the so-called "sphere of influence" of the atom is the actual boundary by which we know the atom and measure its behaviour. Why not call this the actual bulk of the atom?

From another point of view, the ordinary conception of a solid has always seemed to me little short of an absurdity. A gas may very properly be imagined with moving particles far apart, but what could give the rigidity of steel to such an unstable structure? The most reasonable conclusion, from all the evidence taken together, seems to be that the interstices between atoms in solids and liquids must usually be small even in proportion to the size of the atoms themselves, if, indeed, there are any interstices at all.

Very direct and convincing evidence of another sort is at hand. The idea that atoms may be compressible receives striking confirmation from a recent interesting investigation of Grüneisen* concerning the small effect of low temperatures on the compressibility of metals. The average compressibility of aluminium, iron, copper, silver and platinum falls off only 7 per cent. between the temperature of the room and that of liquid air. Extrapolation of the curves indicates that at the absolute zero very little further diminution should occur. As far as we can guess, therefore, the hard metals are almost as compressible at the absolute zero as at room temperatures. But at the absolute zero all heat vibration is supposed to stop; hence this remaining compressibility must needs be ascribed to the atoms themselves. If the atoms are compressible, all mathematical reasoning which assumes them to be incompressible rests upon a false basis. The kinetic theory of *gases* remains unmolested by these considerations, except as they indicate the changeability of b in the equation of van der Waals, but the new views affect seriously the application of this equation to solids and liquids.

Let us proceed to trace a few of the outcomes of our hypothesis. If atoms may really be packed closely together, the volumes of solids and liquids should afford valuable knowledge concerning the relative spaces occupied by the atoms themselves under varying conditions. The densities of solids and liquids then assume a significance far more interesting to the chemical philosopher than before, because they have a more definite connection with the fundamental nature of things. An apparent objection at once suggests itself; if the particles in condensed material are really touching one another, how can we account for heat within the material? Would such closely packed atoms be able to vibrate? The theory of compressible atoms supplies as one of its own corollaries the immediate answer to this question. If atoms are compressible throughout their whole substance, they may contract and expand, or vibrate within themselves, even when their surfaces are prevented from moving by being closely packed together. It is thus possible to conceive of a vibrational effect, even in contiguous atoms, provided we can conceive of these atoms as being elastic throughout all their substance. Agitation sufficient to produce even the Brownian movement might easily exist in such a system.

Clearly there is nothing impossible or obviously contradictory to experimental knowledge in the notion that atoms are compressible; indeed, the old idea of small, hard particles far apart is really more arbitrary and hypothetical than the new conception. The obvious simplicity of the latter is rather in its favour than otherwise, as in Dalton's atomic theory. In general, the more simply a hypothesist interprets the phenomena of Nature the more useful the hypothesis is likely to be, provided, of course, that the interpretation is adequate. The modern philosophy of pragmatism is a good guide in such matters; a theory not obviously illogical should be judged by its usefulness. Let us, then, test the new hypothesis by applying it to other aspects of physical chemistry.

If pressure produces a change in the sizes of the atoms and molecules themselves, may not the actual volumes of liquids and solids be used as a guide to the unknown internal pressures within them? Cannot we thus discover whether or not chemical affinity exerts pressure in its action? To follow this clue the simplest possible case was chosen at first—namely, the comparison of the contractions taking place on combining several elements in succession with a single very compressible one. The changes of volume occurring during the formation of oxides were first computed; later, chlorides and bromides were studied. According to the theory of compressible atoms, we should expect to find greater contraction in cases of greater affinity. A glance at a diagram (Fig. 1) depicting typical data concerning certain nearly related chlorides strongly supports this inference—that is to say, reactions evolving much heat manifest great contraction. Evidently the change of volume in any case must depend not only on the intensity of the pressure exerted by the affinity, but also, among other things, on the compressibility of the substances concerned. The greater the compressibility the greater should be the change of volume caused by a given pressure of affinity. Before any definite conclusion can be drawn the differences in compressibility must be taken into account.

These thoughts led to the measuring of the compressibilities of a large number of elements and simple compounds. The compressibilities of 35 elements and many single compounds were studied with sufficient care to leave no doubt as to their relative values. It became at once manifest that the formation of a compound of a compressible element was attended with greater decrease of volume than the formation of a similar compound of a less compressible element, other things being equal. This is just what the theory leads us to expect, and is a fact inexplicable by any other hypothesis as yet known to me.

Another essential aspect of the theory of compressible atoms is that which concerns cohesion. If the pressure of chemical affinity causes atomic compression, may not the pressure of cohesive affinity also have the same effect? The bulk of evidence strongly indicates that cohesiveness as well as chemical affinity exerts pressure in its action, and hence that each plays a part in determining the volumes occupied by molecules.

Thus the computation of the space occupied by either a solid or a liquid becomes a very complex matter. Not only must the various chemical affinities at work be taken into account, but also the cohesive attraction of both factors and products, and the compressibilities over a very wide range of all the substances concerned. Discoverable parallelism in volume changes is to be expected only when one alone of these forces is the chief variable.

Carried through to its logical conclusion, the idea that atoms are compressible gives one quite a new conception of the molecular

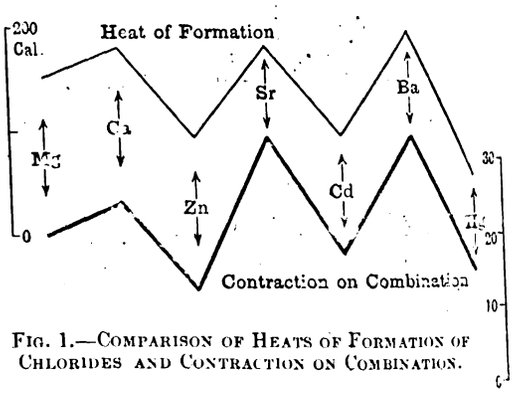

FIG. 1.—COMPARISON OF HEATS OF FORMATION OF CHLORIDES AND CONTRACTION ON COMBINATION.

mechanics of the universe. The influence of atomic compressibilities may be perceived everywhere, and in most cases each fact seems to fit easily and without constraint into its place in the hypothesis. Even apparent exceptions, such as the abnormal bulk of ice, may be ascribed in a reasonable fashion to superposed effects.

Many physico-chemical phenomena assume a new aspect when viewed from the standpoint of this idea. New notions of the mechanism of the critical phenomena, surface tension, ductility, malleability, tenacity and coefficient of expansion are gained. The peculiar relations of material and light, such as magnetic rotation, fluorescence, partial absorption, and so forth, may be referred to the modified vibrations of distorted atoms. The deviations from the exact fulfilment of many older generalisations concerning volume (such as the equation of Van der Waals already cited, the comparative volumes of aqueous solutions, especially of electrolytically dissociated substances, and the variations in the crystal forms of isomorphous substances) are seen to be a foregone conclusion. Moreover, the theory, although not necessarily dependent on the modern belief that atoms are built up of numbers of much smaller corpuscles, is consistent with that belief, for would not such an entity be compressible?

The relation between heat of reaction and change of volume stimulates interest in chemical thermodynamics and curiosity as to the mechanism of the output of energy during chemical change. A search for accurate data wherewith to reason about this question soon revealed the uncertain nature of many of the figures. Here, in the domain of thermo-chemistry, as in those of atomic weights and compressibilities, new methods were needed in order to attain precise results. In thermo-chemical reasoning particularly accurate data possess a significance wholly denied to cruder results. The relations between the heat of formation of organic substances, if determined accurately enough, may be hoped to throw light on

* E. Grüneisen, "Ann. Physik," 1910 (iv.), 33, 1239. The relative values for the compressibilities recorded in this investigation are doubtless trustworthy, although the absolute magnitudes are somewhat uncertain, because they depend on the rather inadequate theory of elasticity.

Digitized by Google

organic structure and the nature of valence. Approximate values are of no use at all for such a purpose. Enough has been done already to suggest relations of a highly interesting sort between heats of combustion, heats of evaporation, compressibility and many other properties; and to add support to the theory of compressible atoms. Moreover, taken in connection with more precise knowledge of the free energy of chemical changes, the new results will permit the evaluation of bound energy, and give results which may decide whether or not bound energy is really a simple function of change of heat capacity, as has been more than once intimated.

A first step towards the collation of all the varying properties, so as to show their many-sided relationships, is clearly to find the way in which each property varies in relation to every other. With this in mind, let us appeal to the irregular system of the periodic classification, which formed the subject of the Faraday Lecture by Mendeléeff 22 years ago. This mysterious index of uncharted tendencies must hide within itself guiding ideas capable of pointing us onward. Clearly each property must receive, not merely qualitative, but strictly quantitative, treatment. With this in mind, let us compare our various facts by plotting atomic weight in one direction and all the other properties in another. Then, by noting the parallelism or antiparallelism of the wavy lines, many relationships may be traced.

In the diagram (Fig. 2) are plotted a number of properties with relation to the atomic weights. Prominent among the lines is the atomic volume curve; below it is plotted the almost parallel line depicting the compressibilities of the solid elements. These are

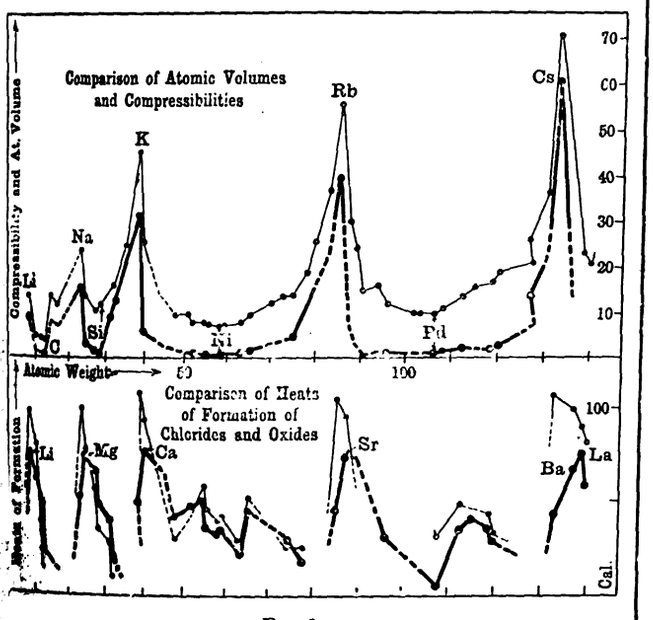

FIG. 2.

seen to be, like the atomic volumes, periodic functions of the atomic weights. The parallelism cannot but suggest that atomic volume and compressibility are fundamentally connected. Another set of waves shows the heat of formation of several compounds plotted with relation to the atomic weights, and a third curve gives the heats of combination of chlorine with other elements, and below it a heavy line depicts the heats of the combination of oxygen with these elements.

The attempt to fathom the nature of these fundamental tendencies leads beyond one's depth into an ocean of speculation. In the blindness of our submerged state we cannot distinguish between cause and effect. The well-known definite relations of the spectrum lines suggest that at least one of the essential requirements for the existence of an atom may be susceptibility to certain definite harmonic vibrations; those compressible atoms capable of vibrating in certain rhythms may be permanent, whilst other aggregations may be unstable. The gap in the periodic system where *ekaiodine* and *ekacæsium* should be, and the amazing instability of the elements immediately following, supports the notion. But here we have a cosmic puzzle for future solution. To-day we lack adequate data, we are blocked at every turn by our ignorance; therefore, the immediate problem is to discover and test each step as carefully as possible. When the facts have been ascertained, man will have a solid basis upon which to build his future superstructure of theoretical interpretation. The quest is not dictated by mere curiosity alone. All organic life is actuated by chemical energy, and exists in a mechanism and environment composed of chemical substances; and the effort to understand these essential conditions of human existence constitutes one of the most important objects of human endeavour. Superficial observation of the complex phenomena of life can do but little; patient study of the fundamental laws of the physical universe alone can help to unravel the interwoven threads. Health, well-being and a profound philosophic outlook are alike dependent upon the result. No one can predict how far we shall be enabled by means of our limited intelligence to penetrate into the mysteries of a universe immeasurably vast and wonderful; nevertheless, each step in advance is certain to bring new blessing to humanity and new inspiration to greater endeavour.

CORCOVADO ELECTRIC RAILWAY.

One of the most recent electric railways installed in South America is the new Corcovado line, which ascends to the summit of Mount Corcovado, in the neighbourhood of Rio de Janeiro. A steam operated line had previously been in operation, and was well patronised by tourists on account of the wide panorama overlooking the city and the bay which could be enjoyed from the summit. Quite recently the line was purchased by the local power company which is concerned with lighting and tramway enterprises in Rio de Janeiro, and the road was equipped with electric traction on the Oerlikon system, following to some extent the method used on the Jungfrau railway.

The electric line starts near the city at a 130 ft. altitude and rises to 2,100 ft., reaching a point near the summit of the mountain. The

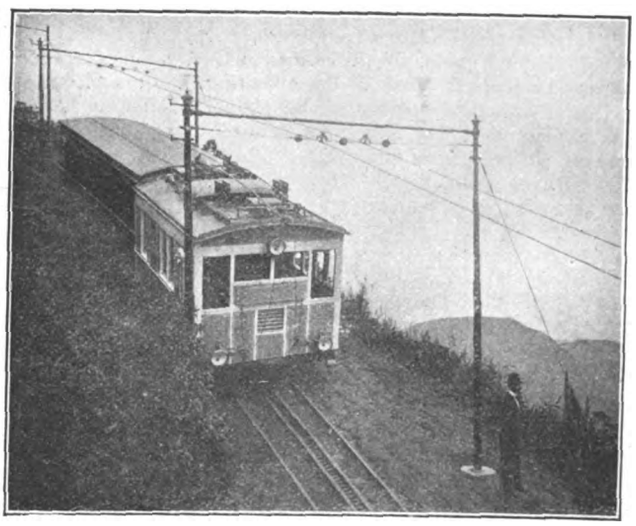

FIG. 1.—CORCOVADO ELECTRIC RAILWAY.

total length is 2·3 miles, of which 68 per cent. comprises curves. Owing to the heavy gradients it is necessary to use the rack-rail on the whole of the line, and the Riggenbach system is adopted. The track gauge is one metre, and between the rails are fixed two channel irons between which are riveted the teeth of the rack.

Three-phase current is employed, and a specially-designed locomotive, which is illustrated in Figs. 1 and 2, was built by the Oerlikon Company. On the roof is a double trolley which takes current from a 750-volt overhead line at a frequency of 50 cycles. Such frequency was already adopted in the local power plant, and even though it is somewhat high for traction work, it was used without any difficulty by properly designing the motors.

Some departure was made from the methods employed on the Jungfrau line. The locomotive is at the rear and pushes the car up the track, but owing to the heavy gradients it was found advisable to keep the locomotive independent of the car, and it does not support any of the weight of the latter, as on the Swiss line. In designing the locomotive, the centre of gravity is brought down as near the rail as possible, and a safety grip is used under the rack rail.

The truck of the locomotive carries two separate pinions which engage with the rack. For each pinion there is mounted a similar set of apparatus consisting of a three-phase motor driving a countershaft by means of reduction gears. The speed reduction is from 11·3 to 1. Each of the motors is bolted down to the top framing of the truck, so that it lies above the inside floor of the locomotive and is quite accessible. The motors have 8 poles, and normally run at

Digitized by Google

730 revs. per min. In the armature circuit of each motor is placed a rheostat for regulating the speed. Both rheostats are coupled together mechanically so as to be operated by a single movement of the controller handle. The two motors are always operated in parallel. Above them is mounted a sheet-iron box of large size in order to contain the resistance coils, and a good air draught for cooling the coils is provided by a motor-driven fan placed in the rear.

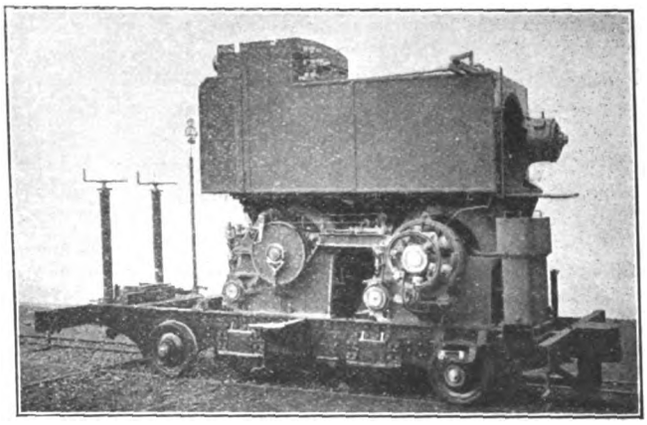

FIG. 2.—VIEW SHOWING CONSTRUCTION OF CORCOVADO ELECTRIC LOCOMOTIVE.

Such air escapes at the front by a vertical flue, which runs up through the roof of the locomotive. On the front of the box are mounted various instruments and control levers.

The resistance coils also serve to absorb the energy when the car is run on the down grade, and the motors are used as generators in order to provide an electric brake. For operating the three-phase motors in this way, there is mounted a small six-pole exciter on the shaft of the rear motor (*see* Fig. 2) in order to furnish direct current. When running under these conditions a double-throw switch disconnects the field winding of both motors from the overhead line, and inserts the fields in the direct current circuit of the exciter. In this way the three-phase motors are made to work as generators upon the resistance coil. A rheostat regulates the amount of direct current in the fields, and accordingly the amount of electric braking. Means are also provided to allow the motors to work as generators upon the line itself, in order to return energy in the usual way, but as the cost of current is quite low in the present case, this point is not one which has as much importance as on some lines. It is found that 40 to 45 per cent. of the energy can thus be regenerated. When descending, the motors can furnish the current needed on the locomotive for the fan motor and also for the lighting.

The company is now operating a 50,000 H.P. hydraulic plant in the region of Rio de Janeiro, using a 44,000-volt three-phase power line. The line ends in a large sub-station in the suburbs of the town, and the present electric road takes its supply from this source. A special sub-station has been installed on the mountain, which sub-station receives 6,300-volt current from the main plant, and reduces the pressure to 750 volts for use on the double-trolley line.

Turkish Telegraphs.—The office of posts, telegraphs and telephones of the Ottoman Empire has been elevated to the rank of a Ministry, and His Excellency Agap Effendi Stamboulian has been appointed Minister.

FARADAY HOUSE AS A TRAINING INSTITUTION.

This is a time of year of great anxiety to parents whose boys have just left school. Some have doubtless decided to make their sons doctors or lawyers, and others, perhaps taking into account the mechanical aptitude displayed by the particular youth considered, have sanctioned his desire to be an electrical engineer. In the case of a lawyer or a doctor, very definite courses of training are laid down and the parent cannot go far wrong; but in the case of the engineer it is different. The parent will find that his son may *apparently* reach his goal in a bewildering variety of ways, and that a decision (by the uninitiated) as to which is the best is difficult, if not almost impossible.

If the parent consults the "Proceedings" of the recent Education Conference for advice he will not be much better off. There he will find almost as many solutions as there were speakers, though if he goes somewhat more deeply into the matter he will discover that it is generally conceded that practical training is essential, and that it is best for the student to combine this in some way or other with his theoretical work.

Such a combination is provided by the Electrical Standardising, Testing and Training Institution in Southampton Row, better known as "Faraday House." The length of the course is four years, although a shorter course can be arranged. The first year is occupied with lectures on electrical and mechanical engineering, combined with practical work in the laboratories, workshops and drawing office. The second year is devoted to the shops and is spent with one of the mechanical engineering firms that are affiliated to Faraday House. During the third year the student once more finds himself back in Southampton Row, and he is now in a position to take full advantage of the advanced course of instruction provided for the third-year students. In his fourth year he is again engaged in practical work, this time with electrical manufacturers, or in a power house. It should be pointed out in this connection that the parent is relieved from all the responsibility of finding a place for his son in works. All arrangements of this kind are made by the Faraday House authorities, and the delay which usually arises at this period is avoided. In fact, by the time the student has finished his first year's course arrangements have been made as to which of the affiliated works he is to attend during his second year. Another important point is that while in works the student remains *in statu pupillari*. Mr. Ernest A. Nash, the secretary,

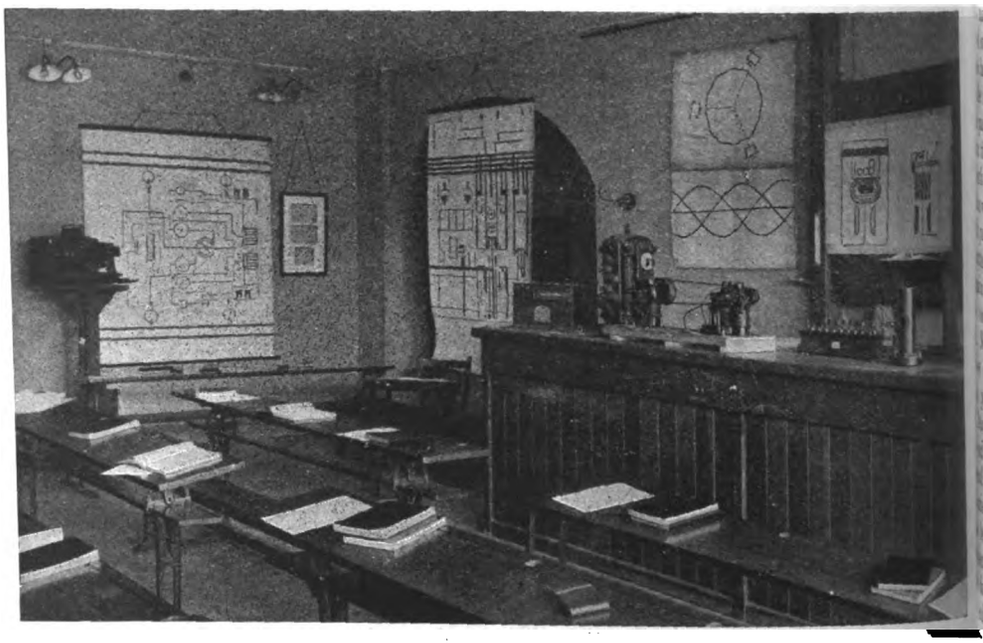

FIG. 1.—ONE OF THE LECTURE ROOMS.

Digitized by Google

of Faraday House, not only receives monthly reports but constantly pays visits to all the affiliated works, and personally satisfies himself as to how each pupil is progressing, both mentally and physically. A third important point to parents is the fact that the fourth or last year of the course is spent in works. The student is therefore right in the way of any

FIG. 2.—THE DRAWING OFFICE.

appointments that may be going. In fact, Mr. Nash informs us that many firms take into their employ these fourth-year affiliated students, being naturally prepossessed in favour of men who have been trained in their own methods.

But the ultimate test of the suitability of any course both from the parent's and the student's point of view is the influence it has on the after-life of the pupil, both as regards technical knowledge and the facility it provides for obtaining further employment. Here again Faraday House can be confidently recommended. Not only do the authorities do their best to obtain a position for each student leaving the college at the end of a complete course—and we are informed that a satisfactory appointment has been obtained for every student who completed his course during last year—but they endeavour to keep constantly in touch both with employers and employés. In this way not only is the properly qualified student reasonably sure of a position, but also, through the help of Faraday House, he is often enabled to obtain an important appointment many years after he has left the college. This valuable feature of the institution is not unlikely to become more valuable in the future. For an increasing number of "Old Faradians" are by this time at or reaching the top of the tree, and they naturally are not averse to applying to their old college to help them to find suitable men. As regards keeping in touch with old students, mention may be made of that excellent publication "The Faraday House Journal." In it are chronicled the appointments obtained by old pupils in a way which must foster the spirit of emulation in those still at the college. There are besides a number of excellent technical articles, all from the pens of old Faradians.

We give examples in the accompanying illustrations of the accommodation provided at Faraday House for the theoretical training of students. On the ground floor and basement are the carpentry, fitting and machine shops and engine room. The second floor contains the physical and chemical laboratories, the battery room and the common room of the junior students. On the third floor are three lecture rooms and two more common rooms, and on the fourth floor is the drawing office. All the rooms are light and airy, desirable features where mental work has to be done, while the whole building is heated by a low-pressure hot-water system.

The basement workshop and engine room has a floor area of about 2,000 sq. ft. and is well lighted by two large skylights fitted with a special glass rendering artificial light unnecessary. Indeed, although it is entirely underground, the light is as good as in some of the upper rooms which get their light direct. At the north end are the lathes, seven in all, including five screw-cutting lathes, also drilling, shaping and milling machines, all electrically driven from shafting attached to a steel frame erected independently of the main fabric, so as to avoid vibration. Running the whole length of the shop under the main

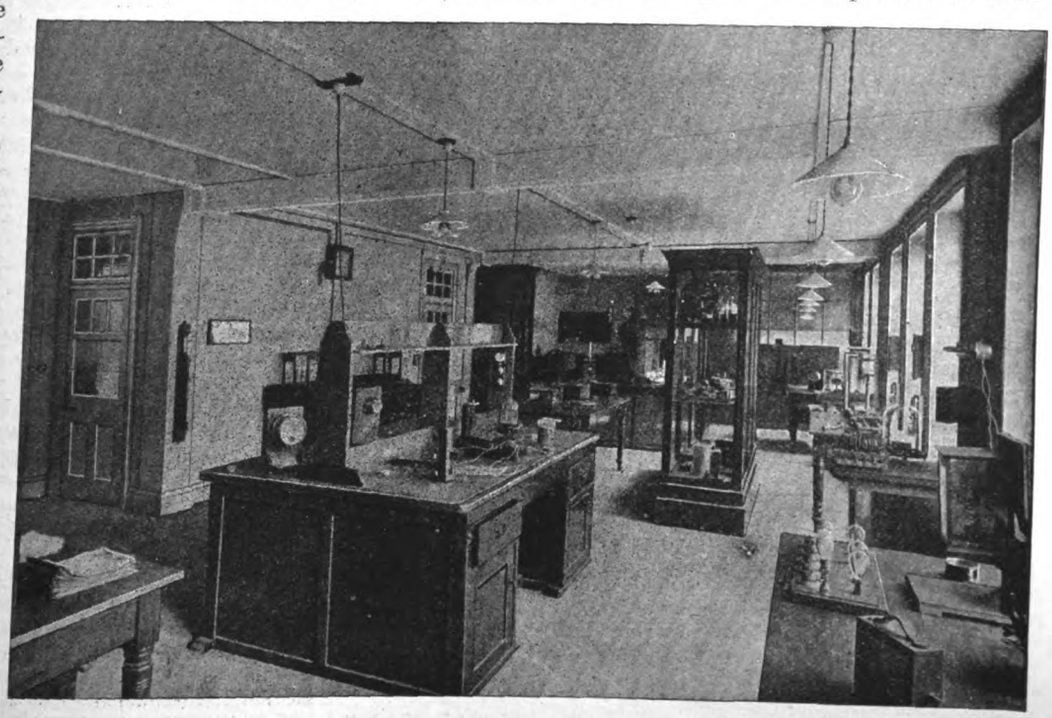

FIG. 3.—THE ELECTRICAL LABORATORY.

skylight is the fitting bench, 55 ft. long. At the south end is the forge, a boiler, steam engine, condenser and pump, a new type of Crossley gas engine with magnetic ignition, four electrical generators, and a De Laval turbo-generator. The upper or carpenter's shop has an area of about 1,200 sq. ft. The main

Digitized by Google

bench, running nearly the whole length of the shop, is 42 ft. long and is fitted with Parkinson vices. The lathes, saw bench, and other appliances for carpentry are here. There is also at the south end an unusual type of motor generator constructed for testing work. It is a special form of alternator direct-coupled to a continuous-current motor having a double commutator. By means of connecting pieces it is possible to obtain either single, two, or three-phase current of any practical frequency, the regulating device of the motor allowing a very wide range of speed. Outside the chemical laboratory, on the flat at the back, is the battery room, containing about 54 large Pritchett cells and about 200 smaller accumulators. The connections allow of a wide range of combination, so that almost any voltage or current can be obtained. The lecture rooms, three in number, are on the third floor; two have a floor area of over 600 sq. ft., the smallest being about 22 ft. by 20 ft. The usual fitted lecturers' benches are provided and all the rooms can with little difficulty be made into one room. It may be of interest to state that when each room is filled with the maximum number of students provided for, the supply of air per pupil is ample owing to the excellent ventilation. The drawing office which is on the fourth floor, is 60 ft. long, the total floor area being at present over 2,000 sq. ft. It is splendidly lighted both back and front, and is provided with accommodation for 70 students. The benches are of a special pattern, having slopes for the drawing boards and lockers underneath that close with a spring catch, so that each student can immediately put away his board, with T-square and instruments, at the end of the lesson, and yet keep it free from dust. Round the room are hung many samples of the materials and parts used in dynamo manufacture.

The physical laboratory is on the second floor and runs the whole width of the building, 60ft., and has an area of 1,600 sq. ft., being well lighted back and front. It is fitted with all the necessary apparatus for making physical and electrical measurements. At the north end, protected by a strong barricade, are two motor generator sets and one rotary converter for experimental demonstrations. An independent system of wiring runs all round the room to provide the current required for testing purposes, whether from the institution generators or from the street mains which supply the building with alternating current at 200 and 100 volts, and direct-current at 530, 200 and 100 volts.

Finally, as a guarantee of the value of the course given, we may mention that Dr. Alex. Russell, M.A., D.Sc., M.I.E.E., is the principal of Faraday House, and that he personally gives lectures to the advanced students both in mathematics and electrical engineering. The regular staff, too, is supplemented by engineers who deliver lectures on subjects in which they are experts, and amongst those who have given regular courses of lectures to the students we may mention, Mr. James Swinburne, F.R.S., Mr. Robert Hammond, M.Inst. C.E., Prof. Carus Wilson, Mr. H. M. Hobart, M.Inst.C.E., Mr. W. R. Cooper, Dr. W. H. Eccles, Mr. John Rennie and Mr. Wallis Jones, M.Inst.C.E.

In connection with Faraday House there is a very flourishing Old Students' Association of which Mr. C. P. Sparks, M.Inst. C.E., and Mr. G. W. Partridge, M.Inst.C.E., are the two senior past-presidents.

PROF. TURNER'S ADDRESS TO SECTION "A" OF THE BRITISH ASSOCIATION.*

THE CHARACTERISTICS OF THE OBSERVATIONAL SCIENCES.

It will doubtless startle my audience to hear that this section has only once in its history been addressed by an astronomical president upon an astronomical topic. The addresses of Sir George Darwin (in 1886) and of Prof. Love (in 1907) on the past history of our earth certainly have an astronomical bearing, but if we distinguish between the classical astronomy and its modern expansions they would be assigned to the latter rather than to the former; and so would the few astronomical allusions in Prof. Schuster's address at Edinburgh in 1892. Even if we include, instead of excluding, all doubtful cases, there will still appear a curious neglect of astronomy by section A in the last half-century, all the more curious when it is remarked that the neglect does not extend to the Association itself, seeing that there have been three astronomical presidents of the Association who had not been previously chosen to fill this chair. The neglect is not confined to astronomy, but extends, as some of us recently pointed out, to the other sciences of observation; and we thought that, as a corollary, it would be better for the section to divide, in order that these sciences might not continue the struggle for existence in an atmosphere to which they were apparently ill-suited. But the section decided against the suggestion, and I have no intention of appealing against the decision. This explicit statement will, I trust, suffice to prevent misunderstanding if I proceed to examine the possible causes of neglect—for I cannot but regard the record as significant of some cause which it will be well to recognise even if we cannot remove it.

Let me begin by quoting from the admirable address—none the less admirable because it was only one-quarter of the length to which we have become accustomed—delivered by my late Oxford colleague, the Rev. B. Price, at Oxford in 1860, wherein he referred to the constitution of this section as follows:—"The area of scientific research which this section covers is very large, larger perhaps than that of any other; and its subjects vary so much that while to some of those who frequent this room certain papers may appear dull, yet to others they will be full of interest. Some of them possess, probably in the highest degree attainable by the human intellect, the characteristics of perfect and necessary science; while others are at present little more than a conglomeration of observations, made indeed with infinite skill and perseverance, and of the greatest value: capable probably in time of greater perfection, nay, perhaps of the most perfect forms, but as yet in their infancy, scarcely indicating the process by which that maturity will be arrived at and containing hardly the barest outline of their ultimate laws." A little later in the address Prof. Price made it quite clear which were the sciences "in their infancy." "And finally we come to the facts of meteorology and its kindred subjects, many of which are scarcely yet brought within any law at all."

There is here much that will command ready and universal assent; but is there not also a rather unnecessary social scale? The science of planetary movement had not yet been "brought within any law at all" (as we now use the term) in Tycho Brahé's time; but was the astronomy of Tycho Brahé socially inferior to that of Kepler? I ask whether there is of necessity any drop whatever from the plane of Kepler, who realised the laws, to that of Tycho, who never reached any suspicion of the true laws, but had nevertheless such faith in their existence that he cheerfully devoted his life to labours of which he never reaped the fruits? Is it not a dangerous doctrine that the work done previous to the formulation of a law is in any way inferior? Consider the case of M. Teisserene de Bort, when he began sending up his balloons. "Show me your laws," cries the mathematician. "But they are just what I hope to find," replies M. de Bort. "Yes, but surely you have formulated some law you wish to test?" pursues the invigilator. "How can I to give you proper scientific rank unless you can produce at least a tentative law?" "On the other hand I wish to keep a perfectly open mind," maintains M. de Bort. "Then I fear I cannot admit you to our class at present; you must join the infants' class, and I can only give you my best wishes that you may reach maturity some day." Unperturbed, M. de Bort continues to send up his balloons, and almost immediately discovers the great fact about the isothermal region which will be a permanent factor in the meteorology of the future. The mathematician is now ready to admit him, as a worthy person who has found a law about the constitution of the atmosphere. But was not the merit in sending up the balloons whatever came of it? Is it not sometimes more courageous to take risks of failure? The mathematician, safe in his stronghold which possesses "probably in the highest degree attainable by the human intellect the characteristics of perfect and necessary science" is like a man who has inherited a good old-established business, and he has a distaste for the methods of those who have to try new ventures. No doubt many who make such trials fail; but on the other hand, great fortunes have been made in that way.

I also take the opening words of Sir G. H. Darwin's address to the section at Birmingham in 1886. "A mere catalogue of facts, however well arranged, has never led to any important scientific generalisation. For in any subjects the facts are so numerous and many-sided that they only lead us to a conclusion when they are marshalled by the light of some leading idea. A theory is then a necessity for the advance of science, and we may regard it as the branch of a living tree, of which facts are the nourishment."

With the utmost respect I wish to question whether the criterion indicated goes deep enough. Often have we had ocular demonstra

*Abstract of the Address delivered by Prof. H. H. Turner, D.Sc., D.C.L., F.R.S., at Portsmouth, yesterday.

Digitized by Google

tion of the value of a theory in stimulating the advance of science, but is advance wholly dependent on the existence of a theory? I have tried to indicate already a deeper motive power by such instances as the work of Tycho, who had no theory, but who perceived the need of observation. And I will now definitely formulate the view that the perception of the need for observations, the faith that something will come of them, and the skill and energy to act on that faith—that these qualities, all of which are possessed by any observer worthy the name, have at least as much to do with the advance of science as the formulation of a theory, even of a correct theory. The president in support of his assertion then described the observations made by Mr. Campbell at the Lick Observatory which, when catalogued in an obvious order, had led to an important scientific generalisation.

Even if the like has never happened before, *this* scientific advance is at any rate due to little more than the accumulation of facts which arranged themselves, as Bacon hoped would naturally happen. But does it detract from the merits of this fine piece of observational work that it was suggested by no leading theory? And I will ask even further: Would its merits have been less if no such immediate induction had presented itself? To this second question I can scarcely expect a general answer in the affirmative; it is so natural to judge by results, and so difficult to look beyond them to the merits of the work itself that I shall not easily carry others with me in claiming that the merits of the observer shall be assessed independently of his results. And yet I affirm unhesitatingly that until this attitude is reached, we cannot do justice to the observer. I believe it will be reached in the future, and I shall endeavour to give reasons for this forecast; but I admit frankly that our habit of judging by results will be hard to break. It extends even to the observer himself, and leads to the withholding of his observations from publication, so that he may himself extract the results from them. In the pure interests of the advance of knowledge, it would be far better to publish the material, so that many brains rather than one might work upon it. But the observer knows that by this course he risks losing almost the whole value of his patient work, which would pass as unearned increment to the particular person who was lucky enough to make the induction.

The illustration will suffice to remind us that the work of the observer is far from being merely mechanical: it demands also skill and judgment—skill in defeating systematic error, and a fine judgment, born of experience, of the success attained. All this is independent of the generalisations which may or may not be arrived at. I venture to think that the great brilliance of Newton has dazzled our vision so that we do not see some things quite clearly. "Had it not been for Newton (writes De Morgan in his 'Budget of Paradoxes,' p. 56) the whole dynasty of Greenwich astronomers, from Flamsteed of happy memory, to Airy, whom Heaven preserve, might have worked away at nightly observation and daily reduction without any remarkable result: looking forward, as to a millennium, to the time when any man of moderate intelligence was to see the whole explanation. What are large collections of fact for? To make theories *from*, says Bacon; to try ready-made theories *by*, says the history of discovery; it's all the same, says the idolater; nonsense, say we!" But nothing of this will fit in with what we know of Bradley's work; he discovered aberration, not by any help fom Newton, but by accumulating a mass of observations. He had no ready-made hypothesis, or rather he had a wrong one, *viz.*, that the stars would show displacement due to parallax; and after this was proved wrong, as it was at the very outset, he had nothing in the way of a theory to guide him, and found great difficulty in devising one *after* he had collected his facts, which spoke for themselves so far as to reveal plainly the essential features of the phenomenon in question.

De Morgan was a mathematician, and I have noticed that mathematicians are apt to be crisp in their statements: but he is a bold man who says "nothing will ever come of it." Perhaps an equally crisp statement on the other side may be pardoned. I adventure the remark that if nothing has hitherto come of such observations, it is because observers have been misled by the very teaching of De Morgan and others who share his views: they have been told that they will do no good without a theory until they have come to believe it; whereas the truth probably lies in a quite different direction. To present my reasons for this proposition I must ask you first to consider in some detail the method of discussing meteorological observations suggested some years ago by Prof. Schuster.

He considers the record of any meteorological element such as temperature or rainfall. When these records are put in the form of a diagram in the familiar way we get a wavy line, which has much in common with that traced by a gramophone needle on a smaller scale. The sight of the complexities is almost paralysing, especially when those who would otherwise attack the problem are deterred by the emphatic assertion that it is useless to do so without the equipment of some guiding hypothesis. Most of the obvious hypotheses have of course already been tried, and the majority of them have failed. It is to Prof. Schuster that we owe the vitally important advice to disregard hypotheses and make a complete analysis of the record. Of course the labour is great, but the genuine observer is not afraid of labour. And in practice the work always resolves itself into a series of finite steps, owing to the finite extent of the observations. This method has been applied to the consideration of spectra, sun spots and other astronomical data.

The method of Prof. Schuster is not the only one that has been recently proposed for dealing with large masses of observations. We have also the methods of Prof. Karl Pearson. These have been far more widely adopted for use than the periodogram, and they have also been more adversely criticised. As regards criticism, I think it is fair to say that it has chiefly been directed towards the nature of the material on which Prof. Pearson has used his process than on the process itself, and at present we need not be concerned with it. The processes themselves are sound enough; one of them, for instance, is much the same as the old method of least squares in a simple form. But if the same criticism is made as has been made on the method of the periodogram—viz., that it is not new—we can reply in almost the same words in the two cases: the mathematical calculus may not be new, the novelty is the insistence on the application of it, and the application to all possible cases. Prof. Pearson ceases to look for one principal factor only, and examines all possible factors, just as Prof. Schuster examines all possible frequencies.

Let us admit frankly that there is an appearance of brutality about such methods. Is our method of search to be merely the old and prosaic one of leaving no stone unturned? We have been led to believe that there should be more of inspiration in it; that a true man of science should have some of the qualities of that fascinating hero of fiction, Mr. Sherlock Holmes, who picks up his clue and follows it unerringly to the triumphant conclusion. Such qualities will do the man of science no possible harm: indeed they will be of the utmost value to him. The point to which I am now calling attention is the chance in nature of the opportunities for using them, which are becoming every day more confused. Dr. Conan Doyle, in the exercise of his art, keeps our attention fixed on a single trail: he conceals from us by mere omission the numerous trails which cross it. We admire the skill of the Indian who pursues an enemy through the trackless forest: but his success depends on the simplicity brought by this very tracklessness, and would be imperilled if there were numerous tracks. It may be remarked, however, that there is a still higher sagacity—that of a hound who even among a number of tracks can pick out the right one by scent. Let us imagine for a moment that the scientific man can be endowed in the future, by training or by some new invention, with a faculty of this kind, so that he may unerringly pursue a single trail even when it is crossed and re-crossed by others. Then in the terms of this metaphor I draw attention to the fact that he has still to determine which is the right trail; and that in general he can only do so by pursuing each in turn to the end. To take an example from recent scientific anecdote: I relate the story as I was told it, and even if incorrect in detail it will serve its purpose as a parable. The Röntgen rays were discovered originally by their photographic action, but afterwards it was found that they would render a screen of calcium tungstate phosphorescent. I was told that this discovery had been made in this wise: Mr. Edison had a large collection of different chemicals, and a number of assistants: he set his assistants busily to work to try each substance in turn until the right one was found. Now this is not only a genuine scientific process, but it is the fundamental process. Let it be frankly admitted that our instincts are against it. We should much prefer to hear that some hypothis had pointed the way, even a false hypothesis such as actually led to the discovery of the possibility of achromatism in lenses. Or if memory had played a part: The other day Prof. Fowler identified the spectrum of a comet's tail with one taken in his laboratory, of which he had some recollection, and our human sympathies fasten at once on this idea of recollection as a praiseworthy element in the discovery. Nay, even mere accident appeals to us more than brutal industry: if Mr. Edison had wandered into his laboratory, picked up a bottle at random, and found it answer his purpose, I venture to say that we should have instinctively awarded him more merit: there would have been just a chance that he was inspired. Let us by all means welcome hypothesis, memory, inspiration, and accident whenever and wherever they will help us: but they may fail, and then our only resource is to help ourselves by the unfailing method of examining all possibilities. The aid of the others is adventitious and comes, like that of the gods, most readily to those who help themselves.

The maxim of "leaving no stone unturned" was enunciated from a rather different point of view some dozen years ago by an American geologist, Prof. T. C. Chamberlin, of Chicago, in a short Paper for

Digitized by Google

students entitled: "The Method of Multiple Working Hypotheses."* After recalling how much the march of science in early days was retarded by the tyranny of a theory formulated too hastily, and how in later times attempts have been made to remedy this evil by holding the theory, provisionally only, as a working hypothesis, Prof. Chamberlin points out that even the working hypothesis has serious disadvantages:—"Instinctively there is a special searching-out of phenomena that support it, for the mind is led by its desires. . . . From an unduly favoured child it readily grows to be a master and leads its author whithersoever it will. . . . Unless the theory happens perchance to be the true one, all hope of the best results is gone. To be sure, truth may be brought forth by an investigator dominated by a false ruling idea. His very errors may indeed stimulate investigation on the part of others. But the condition is scarcely the less unfortunate. . . . To avoid this grave danger the method of multiple working hypotheses is urged. It differs from the simple working hypothesis in that it distributes the effort and divides the affections. . . . In developing the multiple hypotheses, the effort is to bring up into view every rational explanation of the phenomenon in hand and to develop every tenable hypothesis as to its nature, cause or origin, and to give all of these as impartially as possible a working form and a due place in the investigation. The investigator thus becomes the parent of a family of hypotheses: and by his parental relations to all is morally forbidden to fasten his affections unduly upon any one. In the very nature of the case, the chief danger that springs from affection is counteracted." For the further elucidation of Prof. Chamberlin's proposals I must refer my audience to his original Paper, which is well worthy of careful attention. He does not shirk consideration of the drawbacks—"No good thing is without its drawbacks," he writes. And it may be added that no good thing is entirely new, or entirely old. Perhaps it is better to say that it is generally both new and old. The "Method of Multiple Hypotheses" is new because it is still necessary to remind scientific workers of all kinds that so long as they restrict themselves to the examination of one hypothesis only they can never reach complete logical proof: they can only attain a high measure of probability. What is often called verification is not complete proof, but only increase in probability: for complete proof it is necessary to show that no other hypothesis will suit the facts equally well, and thus we are bound to consider other possible hypotheses even in the direct establishment of one.

But the method is also old in that it has long been adopted in practice, however partially and unconsciously, by scientific workers of all kinds. When a boy at school I began to make physical measurements under Mr. J. G. McGregor (now Professor of Physics at Edinburgh) I learnt from him one golden rule: "Reverse everything that can be reversed." The crisp form of the rule may be new to many who have long used it in their work: and its use is simply that of "multiple hypotheses." For when the current in a wire is reversed, the hypothesis is tacitly made that the effect observed may be due to the direction of the current: and when a measured spectrum photograph is turned round and re-measured, it is an admission of the hypothesis that the direction of measurement may be partly responsible for the observed displacements of the spectrum lines. By the various reversals we endeavour in Prof. Chamberlin's words, "to bring up into view every rational explanation of the phenomenon in hand" which can be brought up into view in this way. But truly "no good thing is without its drawbacks," and one drawback to the recognition of this principle is that, by a process of mental confusion, it seems sometimes to be regarded as a distinct merit in a piece of apparatus that it can be reversed in a large number of ways. It must be remembered that the hypotheses thus examined and ruled out are chiefly instrumental ones superadded to those of Nature: and the latter are already sufficiently numerous, without our ingenious additions.

The view which I have endeavoured to put before you of the inevitable course of scientific work is that it will depend more and more on the patient process of "leaving no stone unturned." It may not be an inspiring view, but it should be at least encouraging, for it follows that no good honest work is thrown away. And it is just this encouragement of which the observer, as opposed to the worker in the laboratory and the mathematician, stands sometimes in sore need. The worker in the laboratory can often clear away his hypotheses on the spot, he can reverse his current then and there; but this is often impossible for the observer, who can and does reverse his spectrum plate for measurement, but to reverse the motion of the earth which affected the lines must wait six months, and to reverse also the motion of the star may have to wait six years, or 60, or 60,000. In many cases he must leave the reversal to others, and thus not only can he not test all his hypotheses, but he may not even be able to formulate them. His aim cannot therefore be to establish within his lifetime some new law, and his work is not therefore to be appreciated or condemned by his success or failure in this respect. There are truer aims and surer methods of judgment. Something is inevitably lost when we endeavour to express these aims in the concrete; but for the sake of illustration we may say that the true observer is always endeavouring to reach the next decimal place, and is ever on the alert for some new event. Of the pursuit of the next decimal place it is needless to say more: the aim is as familiar in the laboratory as in the observatory. But I often think that the recognition of new events is scarcely given its proper place in the annals of science, if we have due regard to the consequences. I have protested that in much of his work the observer cannot be judged by the fruits of his labour, though there is an instinctive tendency to judge in this way; but here is a case where he might well be content to be so judged, and yet the consistent award is withheld. Think for a moment of the very considerable additions to our knowledge which have accrued from the discovery by Prof. W. H. Pickering of an eighth satellite to Saturn. The discovery led directly to the recognition of the retrograde motion, and to explain this we were led to revise completely our views of the past history of the solar system. Incidentally it stimulated the search for other new satellites, resulting in the discovery of a curious pair to Jupiter, and next of the extraordinary eighth satellite; while it was the investigation of the orbit of this curiosity which suggested an eminently successful method of work on cometary orbits. If we judge scientific work by its results we must take into account all this subsequent history in our appreciation of Prof. Pickering's achievement. But whether we do so or not is probably a matter of indifference to him, for the true observer is above all things an amateur, using the word in that splendid sense to which Prof. Hale recently introduced us. There have been many attempts to define an amateur. One was given by Prof. Schuster in his eloquent address to this section at Edinburgh in 1892:—"We may perhaps best define an amateur as one who learns his science as he wants it and when he wants it. I should call Faraday an amateur." We need not quarrel with his definition and certainly not with the noble instance with which he points it. But after all I prefer the definition of Prof. Hale:*—"According to my view, the amateur is the man who works in astronomy because he cannot help it, because he would rather do such work than anything else in the world, and who therefore cares little for hampering traditions or for difficulties of any kind."

The wholly satisfactory nature of this view is that it provides not only a definition, but an ambition, and a criterion. We feel at once the ambition to become amateurs, for I deny stoutly that the distinction is conferred at birth: it comes with work of the right kind. And we may know what is work of the right kind by this if by nothing else, that by diligently performing it we shall become amateurs who find it impossible to stop, "who work in astronomy because we cannot help it." Before an army of such men even the vast hordes of dusky possibilities of which we are beginning to catch glimpses must yield. The fight may seem, and no doubt is, without end; and the opportunities for glorious deeds by which outlying whole troops of the enemy are demolished at once are becoming rarer. We are confronted with the necessity of attacking each possibility singly, which threatens the stopping of the conflict through sheer weariness. Clearly the army of amateurs is the right one for the work; weariness cannot touch them, they will go on fighting automatically because "they cannot help it."

THE ELECTRICAL WORK OF THE PHYSIKALISCH-TECHNISCHE REICHSANSTALT IN 1910.†

The electrical work at the Reichsanstalt during 1910 may as usual be divided into two parts, the purely routine tests on instruments and apparatus, and the researches undertaken with a view to improving the present methods of measurement or to increasing the present state of our knowledge of the physical properties of the materials employed in electrical work. We give below some details of the researches made in the latter division.

The joint work carried on in the National Physical Laboratories of Germany, England and the United States under the *ægis* of the International Commission for Electrical Units and Standards was begun at the Reichsanstalt in 1910 under the direction of Dr. Jaeger. The most important part of this work was the determination of the E.M.F. of the Weston standard cell to within 1/10,000th part of the value given by the International Ohm and Ampere as fundamental standards. As a result of measurements with the silver voltameter undertaken at Washington, the delegates found that the com-

ponding value for the E.M.F. of the Weston cell was 1·0183 international volts to within 1/10,000th part. It was therefore agreed that from January 1, 1911, the value of the Weston cell should in all international laboratories be considered as 1·0183 volts at 20°C. This required an alteration of 0·0003 volts in the standard German value, the value formerly being 1·0186 volts. This alteration is due to the fact that the mercurous sulphate in the new cells has a somewhat lower electromotive force than that hitherto used at the Reichsanstalt.

During 1911 a sum of 283,400 marks (£14,170) was granted for the erection of a new "heavy-current" electrical laboratory, and of 111,500 marks (£5,575) for the erection of a telegraph laboratory, which is to be free from magnetic disturbances, at Potsdam.

The experiments on the variation of standard Weston cells which were carried out in conjunction with the National Physical Laboratory and the Bureau of Standards have been continued during the past year. Similar researches have been conducted on the silver voltameter.

The four manganin resistances which have been employed for some years past as secondary standards were during 1910 frequently compared with each other and with other resistances; and appeared to have remained constant within the limits of observational error. The 1 ohm manganin resistances were during July 1909 placed in an atmosphere of 50 per cent. humidity from which they were only removed for measurements to be made on them. Arrangements have now been made for these resistances to be tested while they are actually in the humidifiers. As is well known, moisture has a certain effect on the resistance of wire resistances, though with those whose value is of the order of 1 ohm it is not considerable (under 1/100,000th of an ohm). The influence of damp upon the secondary standards cannot be determined with any accuracy as the variations are so small.

In February, 1910, seven mercury rectifiers were installed for charging a 120-volt battery off a three-phase circuit. The maximum capacity of each rectifier is 10 amps. To maintain the current at this value two iron wire variators in parallel are placed in the cathode circuit. These variators have a choking effect so that while the voltage varies from 10 to 40 volts, the current remains constant at 5 amps. In this way it is possible to operate several rectifiers in parallel for charging the same battery. The rectifiers are divided into two groups of three and four respectively, so that it is possible to charge two batteries at the same time at different voltages. In general, however, all seven rectifiers are connected in parallel. Charging can thus go on both day and night without any attendance being necessary, and the cost of the energy used in the variators is therefore more than set off by the saving in attendants' wages. Further, so long as the batteries were charged off rotary machines there were never sufficient batteries for the work in hand, but since rectifiers have been installed, by the employment of which charging can go on all night, the number of batteries has been quite sufficient for all purposes.

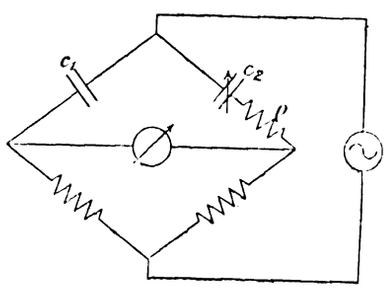
Tests have also been carried out to determine the most suitable arrangements for testing transformer oils. Spheres of 10 mm. and 15 mm. diameter were used as electrodes as well as pin points. With very dry and clean oil the breakdown voltage between the points was somewhat lower than with spheres. The difference, however, disappeared as the distance between the electrodes became greater. As the distances were increased in damp oil a higher breakdown variation was noticed between points than between spheres, but the values were often very irregular. Probably in this case the strong electric field at the end of the points played some considerable part. It was noticed that when a high voltage had been impressed between electrodes placed a long distance apart for a considerable time, the breakdown voltage for a specific distance apart of the electrodes was considerably higher than when a previous high-voltage stress had not been impressed. With the 10 mm. sphere electrodes the measurement of distances was easier and more accurate than with points. These researches are being continued.

Up to the present, certain difficulties have been experienced in making arrangements for testing the breakdown voltages on substances, such as bitumen, which are used for covering in cables. If a mass of the substance is poured on to a smooth metal surface considerable sparking takes place round the edges of the mass, resulting in heating and premature breakdown occurring. An apparatus was therefore devised so as to imitate as nearly as possible the conditions which exist in actual practice. For this purpose an iron tube, 15 mm. in diameter and 10 cm. long, was used, the ends of which were widened out cylindrically. A 40 cm. cardboard tube was then slipped over this arrangement so that the iron pipe was wholly enclosed in the cardboard. A 9 mm. brass rod was next fixed into this arrangement by means of two corks, so that the brass rod was concentric with the iron tube, the two being protected by the cardboard. The iron tube was then filled with the material for testing through an opening in the upper cork. In this way a mass of insulating material about 3 mm. thick was obtained between the brass rod and the iron tube. The cardboard prevented sparking from the iron pipe to the brass rod through the air, the iron and the brass forming the two electrodes for testing. Tests made on this arrangement agreed pretty well amongst themselves.

A series of tests was also carried out on plates of insulating material to determine the energy losses in dielectrics. About ten such plates were interspersed with copper foil, the whole making up a condenser, C_1, with a capacity of from 0·004 to 0·07 mfd. This was connected in a Wheatstone bridge, as shown in the accompanying diagram, C_2 being a variable air condenser which was connected in series with an adjustable resistance. From the value of the condenser, C_2, of the resistance, P, and the frequency, the angle by which the voltage and current in the condenser, C_1, differed from 90 deg. could be determined. Tests were carried out on this arrangement for frequencies between 9 and 2,000, and it was found that the variation in capacity in the case of some substances was only dependent to a slight extent on the frequency, while in other cases the variation was considerable. Sometimes the phase difference also depended on the voltage used, but not always. These researches are being continued.

For measurements such as those mentioned above, resistances free from capacity and self-induction are very desirable. For this reason researches were undertaken on various types of liquid resistances. Numerous solutions were tested and some were found which gave satisfactory results.

Earlier tests which were undertaken on the increase of resistance of single layer coils with the frequency were extended during the year to coils with two and more layers. The interdependence of resistance on the frequency was determined and the results of tests have already been published. During 1910, for the first time, an ammeter was made for measuring high-frequency currents up to 40 amps. A hot wire air thermometer was used for its standardisation and some tests on the optical method of current measurement similar to those of Orlich were made with glowing platinum foil. The agreement was satisfactory enough for the purpose.



It has been ascertained as a result of conductivity tests on copper which have extended over a number of years that there is proportionality between the temperature coefficent and electrical conductivity. For example, an approximate formula is $a_{15} \cdot c_{15} =$ a constant, a_{15} being the temperature coefficent, and c_{15} the specific resistance in ohms per mm. cube at 15°C. The mean value for the constant for all types of copper tested at the Reichsanstalt since 1905 is $6{\cdot}7_8 \times 10^{-5}$. The same relations also apply to aluminium and iron, the constant being different in each case.

Some experiments were made to determine the amount of water absorbed by certain insulating oils and in the course of these researches it was found that the product termed commercially "transformer oil" absorbs but slightly more water than petroleum. The absorption of water at 18°C is for paraffin oil 0·003 per cent., for petroleum 0·005 per cent., and for benzol 0·05 per cent.

As a continuation of the experiments on fuses mentioned in last year's report, researches were made on the influence of high-voltage and the filling material. Silver wires 0·1 mm. in diameter and 150 mm. long were stretched through 15 mm. glass tubes and 200 mm. long, the tubes being filled with dry sand. A current density of 4 amps. per sq. in. was used, the mean temperature of the wire being then 230°C. A number of these fuses were tested with a current of 4 amps. and others with 2 amps. the frequency being 50 in each case. Tinfoil was pasted round the glass tube and an alternating-current pressure of 4,800 volts was applied between the tinfoil and the fuse wire. In these two cases an increase of resistance of the fuse was noticed, the increase being very rapid in the case of the higher currents and amounting to as much as twice the original amount. These wires fused in 10 days. In the case of a current of 2 amps. increase and fusion were less rapid. This increase is attributed to the powdering of the wire. In the case of fuses tested at a pressure of 600 volts with a current of 4 amps., the resistance increased from 10 to 20 per cent. in eight months and fusion did not occur. Overloading fuse wires causes less corrosion when they are enclosed than when free to the atmosphere. In the latter case the convection seems to cause oxidation.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free,
Canada	28s. 3d.	14s. 6d.	7s. 6d.	payable
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	in advance.

New volumes of "THE ELECTRICIAN" *commence in April and October.*

(This charge includes all the numerous Supplements.)

Vols. I to LXVI. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Jan. 31st in each year for the next following edition) 8s 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s; Europe, 2s; U.S.A., 3s. 6d; other countries, 2s. 6d. *Digest of Contents of the* 1911 *Edition sent free on application.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Reduction on quantity.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A Fleming. Vol. I., 12s. 6d. nett. Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gelpel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.; post free, 2s. 3d.

SOME OF THE EFFECTS OF COMPETITION.

In the days when the so-called Manchester School of politics flourished, ideas which now seem a little crude found ready acceptance. The pure and undiluted doctrine, as then preached, has almost passed into oblivion, and is now generally associated with rather elderly people of a somewhat philosophic turn of mind. In saying this, we do not mean to pour contempt upon it; it had its virtues and could be supported by many arguments, which were often a little embarrassing to the controversialist, but none the less it represented at best a partial view of things, no longer compassing the whole field of a more highly evolved state of commercial activity.

Perhaps one of its most cogent arguments was directed to prove that under conditions of unfettered competition everything would be for the best. Much that has lately happened, quite apart from acute political controversy, seems to show that it is now recognised that competition without compromise is neither in the interest of buyer nor seller, of consumer nor producer. A case in point may be found in the cessation of cut-throat rivalry between the various agencies competing for the traffic of London, a commercial interest which seems likely to be profitable to all concerned if due regard is had to the public weal in any scheme that may be evolved for the purpose of suppressing useless competition. The same policy is being followed by the railway companies of the kingdom, with results which seem likely to be beneficial.

In the electrical world complaints are frequently heard that there are too many in the business, but no remedy has

Digitized by Google

been propounded, and none seems likely, short of the survival of the fittest. Still it is not with this phase of the problem that we are at the moment proposing to deal. Quite apart from this there has been some acute and bitter controversy between electrical and gas engineers. We hope we have at no time done anything to embitter the relations between us and them; they have undoubtedly as much right to conduct their business in their own way as we have to conduct ours.

Still it is pleasant to be told that the effect of this competition between the gas and electrical interests is all for our good. In making this seemingly paradoxical assertion, we are going on the assumption that the state of affairs in Germany is similar to that in this country. The electrical fraternity in Germany owes a debt to Herr DETTMAR, who contributes from time to time to the technical Press a review of the state of progress that is being made in that country. His articles are not altogether suitable for reproduction in our columns, seeing that they appeal to facts, details and statistics that do not apply to Great Britain. It seems unfortunate that we cannot produce somebody who could do the same for us, and devote a certain amount of leisure time to a painstaking analysis of the masses of figures that are to be found in official and technical publications and that might form the raw material for much edifying discourse on the progress that is being actually made, its causes and effects, together with useful hints that might help to encourage the optimist and confound the pessimist.

Herr DETTMAR's latest thesis seems to be to the effect hat greater development of electricity supply has taken lace in those towns in which there is competition from the as works than in those in which no gas is supplied. This ems at first a rather startling assertion. None the less, he alyses facts by subdividing the towns in Germany cording to these two categories, and, further, according to eir populations. Undoubtedly the towns in which there no gas supply but which have an electricity supply are the whole small, but there appear to be nearly 100 of ese in all. The comparison is made on the basis of watts r head of the population, and the state of affairs in 1900 contrasted with that in 1909. It seems that in these all places, none of which has a population exceeding 000, a good start had been made in 1900 on the watt-sis, all the stations included in the statistics having been work for at least two years (this proviso being made to clude mere chance growths of a few weeks). The progress ich was made between 1900 and 1909 was gratifying, the its per head of the population having nearly doubled on average. On the other hand, in the towns in which works already existed, amounting in all as far as central tions are concerned to 72, a much less hopeful start s made on the watt-basis, especially in the bigger towns h populations over 50,000. But here the progress has n on a much larger scale, and in the towns with a popula- of more than 100,000 the output per head of the popu- on has increased more than four-fold. This does not, ourse, necessarily mean that the output per head is at ent much greater in the one case than in the other; in fact, the figures in the two cases are very similar; but the differential coefficient, so to speak, or in other words, the rate of progress, differs, and this leads us to think that it will continue to vary, probably in a way that should be encouraging to the electrical engineer. Herr DETTMAR is unable to give any very precise answer to those who ask what has been the effect of electrical competition on the gas interests. He says that their statistics are often vague and lacking in precision; but on the whole there seems reason to think that their output may in some cases have increased slightly, if estimated on the same basis; but in others there has probably been a small loss. In so far as our own interests are concerned, it is not perhaps difficult to understand some of the causes that have contributed to electrical progress in the larger towns, where gas is already in the field. And the absence of these causes in the smaller towns, such as greater competition with one's neighbour and perhaps a higher standard of comfort, may explain why in the country districts progress is slower, though the start promises better things. Undoubtedly, other reasons besides the mere existence of gasworks in a place could be adduced to show why a larger field is likely to be more profitable than a more confined sphere. But probably sufficient has been said to enable us to see that the pioneer work which was done by the gas engineers in ousting paraffin lamps and candles has not been without its beneficial effects on electricity supply.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Dynamo Electric Machinery. DIRECT CURRENT MACHINES. 8th edition. By S. SHELDON and E. HAUSMANN. (London: Crosby Lockwood & Son.) Pp. ix. + 328. 12s. net.

The later editions of many works consist simply of reprints of the earlier editions with a few alterations and additions. As a result much matter is still included which deals with practices rendered obsolete, and which would probably not be included in an entirely new work. This failing is only too often noticeable with text books on dynamo-electric machinery, the examples and illustrations of machines being frequently anything but up to date.

It is, therefore, very pleasing to note that the authors have revised their book in a most thorough manner. With the exception of the first two chapters—devoted to electrical and magnetic laws and facts—the book has been entirely rewritten, and practically the whole of the illustrations are new.

In the previous editions chapters were devoted to the design and testing of machines. These have now been omitted. We agree with the authors that the subject of the design of continuous-current machines is too vast to be adequately treated in a book of this type, but think that a small chapter on testing should have been retained, dealing with the more ordinary tests in common use.

The subject matter is divided into nine chapters, the first two of which contain a concise *résumé* of general electrical and magnetic principles, and the electrical and magnetic properties of materials. The third chapter deals with the rotating portion of continuous-current machines, both from the theoretical and practical point of view. The authors have contented themselves with describing modern practice, with the result that ring windings and smooth core armatures are barely mentioned. The fourth chapter is devoted to the field system and the calculations connected therewith. The following chapter deals with armature reaction and commutation. The

Digitized by Google

theory of commutation is gone into at very great length. We are surprised to find that the use of auxiliary poles is stated as rather to reduce armature reaction than definitely to assist commutation. As a matter of fact, it can hardly be claimed that the effect of the interpole is materially to reduce armature reaction, for its action is confined to a very small portion of the armature midway between the main poles. The true function of the commutating pole is to provide a correct commutating field in the armature coils undergoing short-circuit. To effect this the M.M.F. on the commutating pole must be such as more than to counterbalance the armature M.M.F. acting at the geometric neutral position.

The two next chapters deal with generators and motors respectively, and contain much up-to-date information. The generator speeds for direct-coupled machines are low compared with English practice. The remaining chapters deal with motor generators, boosters and storage batteries and central station equipment, and call for no especial comment.

The book is to be recommended as a very good text book on continuous-current machines. The information given is reliable and typical of modern practice, and the purely theoretical parts are put forward clearly. Inch units are used, which causes the magnetic calculations to appear unfamiliar to those of us who use the C.G.S. system. A. E. C.

Electricity in the Service of Man. By R. Mullineux Walmsley, D.Sc. Vol. I.—"The History and Principles of Electrical Science." (London: Cassell & Co.) Pp. xv.+828. 7s. 6d. nett.

One hardly knows what to expect on opening a book with such a title. Twenty or thirty years ago the practical applications of electrical science were few, and there existed an enormous field of electrical phenomena and theory, which seemed to have no prospect of practical application or public utility. To-day this is all changed; the pretty-coloured Geissler tubes have developed into the X-ray apparatus, the electromagnetic waves, which appeared to be little more than an elaborate toy for mathematicians, are now among the commonplaces of our everyday life. To whichever branch of electrical science we turn, it can very properly be described as "Electricity in the Service of Man." It is useless trying to give anyone a reasonable idea of the many applications of electrical science without a certain amount of grounding in the fundamental principles involved. The title "Electricity in the Service of Man" is, therefore, broad enough to include practically anything which the author cares to put into it, so that we are not surprised to find that the volume under review deals with almost everything electrical, including lightning, which can hardly yet be said to have been impressed into "the service of man."

The book is, of course, a new edition of an old and well-known work. It has been very largely rewritten to bring it into line with our present knowledge of the subject. This has increased the bulk so greatly that it has been found necessary to divide the book into two volumes, of which that under review is the first. It deals with the history and principles of electrical science while Volume II. will deal with practical applications and their technical details. The present volume contains over 800 pages and 800 illustrations. After a brief historical survey of the subject down to the beginning of the last century, the first chapter deals with the elementary principles of magnetism and then, somewhat fully, with terrestrial magnetism. Then follows electrostatics, including influence machines, electrophori, Leyden jars, &c. The succeeding chapters deal with primary batteries, thermo-couples, Ohm's law, electrolytic action, secondary cells, heating effects of the current, glow lamps, arc lamps, magnetic properties of iron, electromagnets, instruments and simple measurements, telegraphy and telephony, transformers and induction coils, dynamos, motors, alternators, converters (under the somewhat unusual name of kinetic transformers), sparks, vacuum tubes, and their applications. The book concludes with a chapter on more advanced measurements and instruments. We are pleased to see that the chapters on such subjects as lamps and magnetic properties of iron are quite up to date, and give the reader a good idea of the recent advances made in these branches. One is surprised not to find among the applications of the electromagnet a description and illustration of the lifting magnets so much used in iron works at the present day, but this is probably reserved for the second volume.

One could hardly expect a book of this nature and size to be entirely free from imperfections. We notice that the description of the single-pivot galvanometer on page 721 seems to refer to a figure which is not reproduced, as the reference letters are not to be found on the figures given. All curves should have clearly marked on them the units in which the quantities are plotted. On page 756 is a sheet of curves giving the resistances of different metals at various temperatures. It is pretty obvious that the temperatures are in degrees centigrade, and a reference to the letterpress confirms this. No clue is given to the units in which the resistance is measured, but by referring to copper we find that at 0°C. its specific resistance is 1,500, from which one concludes that it is given in absolute units. This should be marked on the curve and not left to calculation or inference.

For the book as a whole, however, we have nothing but praise. It is a storehouse of well-arranged and clearly expressed information and can be confidently recommended.

G. W. O. Howe.

L'Établissement des Lignes Aériennes de Transport d'Énergie Électrique. By Octave Cahen. (Paris: H. Dunod & E. Pinat.) Pp. 308. Fr. 9.

This book deals with the preliminary matters inseparable from all transmission schemes with aerial conductors. Naturally the interpretation of the legal enactments in this province come in for the greatest attention, but the technical requirements are also carefully treated. Indeed, this is the only part of the book likely to be of immediate interest to English readers, unless they are inclined, in a spirit of sympathy, to examine the voluminous restrictions that hedge about the transmission problem in France. The original laws, with their subsequent modifications and supplementary decrees, dating from 1888-1910, make a very formidable list, and their detailed recital takes up nearly 200 pages of an appendix.

Legislation affecting electric lines in France is mainly concerned with those transmitting power in bulk at high pressures, the others being more leniently dealt with. The author assumes that the pressure and system, number of conductors, &c., have already been settled, and that, until constructional work is actually commenced, the engineer will be engaged in co-ordinating the legal and engineering conditions so as to secure the best results.

The author very properly insists on the importance of the preliminary setting out or "piquetage" of the line, so as to avoid contravention of any of the State or local regulations, and to ensure that when completed it will be a success as regards its capital cost, working and maintenance. The engineer who has charge of the survey of a line of any length must be familiar with the materials and construction necessary, the laws controlling national and other roads and the procedure to be followed when the line crosses private property. "Piquetage" being, as the author says, the corner stone of the transmission problem, it is essential to apply in its service an expert knowledge of law and engineering and the gift of tact.

The technical side of the survey, dealing with alignments, curves, angles, crossings of railways and telegraph lines, lopping of trees, &c., is a subject of considerable interest, and furnishes some guidance to practice elsewhere than in France. The book as a whole, however, is scarcely one to be bought by an English engineer, unless he is of distinctly altruistic temperament in his professional outlook. J. R. D.

Beanspruchung und Durchhang von Freileitungen. By Roger Weil. (Berlin, 1910: Julius Springer.) Pp. 106. M. 4.

This work is a very instructive and able mathematical treatise on the calculation of the strains and sags of aerial conductors, and will be found of great use by all who have anything to do with overhead line construction. It contains 12 chapters. In the first the author discusses the governing factors of the problem and shows that the starting-point for all calculations is the consideration of the maximum strain in relation to its

Digitized by Google

change and that of the sag with temperature and extraneous loads, such as ice, snow and wind pressure. The fundamental equations are given in Chapter II.; the most important laws on maximum strain and maximum sag are investigated in Chapter III., and in Chapter IV. the fundamental equations and their practical application are carefully discussed and explained.

In this chapter, on page 18, we note what is evidently a slip, or printer's error, in the mathematical investigation of the existence of a point of inflection in the curve given by equation (9') on page 14. The equation on page 18 reads

$$fu''(f \pm n) = 2a_9 - \frac{2b_9}{(f \pm n)^3} = 2a_9\left[1 - \frac{b_9}{a_5 f^3 + 3fn^2 \pm (3f_x^2 + n^3)}\right].$$

The coefficient a_5 in the denominator of the fraction in the right-hand of the equation should be a_9—not a_5—and should multiply all the other terms of this fraction, thus:

$$= 2a_9\left[1 - \frac{b_9}{a_9[(f^3 + 3fn^2) \pm (3f^2n + n^3)]}\right].$$

In Chapter V. numerical examples are completely worked out by the aid of the formulæ given in the preceding chapters. It contains some very interesting results which are also embodied in curves.

The author shows in Chapter VI. how to determine the maximum sags for the most important conductors for spans up to 300 metres (328 ft.) An important case is then considered separately in Chapter VII., namely, the maximum sag of a steel wire or rope from which a cable is suspended.

A simple graphical method of solution of the general problem is next given in Chapter VIII., and the application of this graphical method to hard copper wires is given in Chapter IX. which also includes several instructive curves. The influence of the points of support at different heights are considered in Chapter X., and the case of wires suspended between flexible points of support are investigated in Chapter XI. In the final chapter the numerical and graphical methods are then compared. Two tables of curves are also given at the end of the book. Table I. gives the maximum sags for copper and aluminium wires for all spans up to 300 metres, based upon the rules (Normalien) of the Verein deutscher Ingenieure, while Table II., to which is attached a so-called "cover" table on tracing paper, enables the values of the strain and sag for any particular temperature without accessory load to be ascertained for a copper wire, and the method of using this table is explained by means of an example.

The book contains a large amount of useful information, and the author has carried out his investigations into the problem with considerable skill and success. It deserves close study.

H. G. S.

The Slide Rule. A Practical Manual. By C. M. Pickworth. 12th edition. (London: Whittaker & Co.) Pp. 118. 2s. net.

In this edition of the "Slide Rule" six pages have been added in an appendix on new slide rules, but otherwise the book remains the same as before; so that the new edition is practically a reprint. The book may be recommended to students and others who are anxious for help in using the slide rule and wish to know more of its possibilities. It evidently meets a demand, judging by the large number of editions which seem necessary.

RECENT PHYSICAL RESEARCH.

IX.—THE PRESSURE OF RADIATION.

BY D. OWEN, B.A., B.SC.

§1. When, early in the seventeenth century, Kepler pointed to the pressure of sunlight as the possible cause of the deflection of cometary tails away from the sun, he offered a suggestion that was quite reasonable on the corpuscular theory of light, which was then in vogue. Many efforts were made to put the corpuscular theory on a better footing by establishing experimentally the existence of a force of repulsion by light. De Mairan, the famous observer of the phenomena of auroras, for example, tried such experiments in or about 1754, but without success. Later, the failure of such efforts did duty as an argument against an "emission" theory.

In 1873 Maxwell pointed out, as a deduction from his electromagnetic theory, that light waves should exert a pressure upon objects on which they fall, in amount equal to the energy density, or radiant energy in unit volume. A few years later Bartoli deduced from entirely new considerations the existence of such a pressure, and started an idea which has proved very fruitful in the province of thermodynamic theory. However, many years were permitted to elapse before experimental proof of the reality of such forces was secured. Crooke's researches on the radiometer between 1873 and 1877 had revealed the play of considerable forces, but, as Tait and others showed, these are only indirectly caused by the incident light, being the result of molecular bombardment by the surrounding gas on unequally heated surfaces. This molecular action may be thousands of times in excess of the pressure of the impinging light as calculated from the energy density. The radiometer effect and the influence of convection currents together constitute a gas action which in the earlier experiments effectually barred the way to any demonstration of a light pressure. In 1900 Prof. Lebedew, of Moscow, announced that he had succeeded in isolating and measuring this force. Nichols and Hull, in America, quickly followed, securing a remarkable degree of agreement of observation with theory. Prof. Poynting, in this country, has conducted a series of beautiful experiments on the tangential forces due to oblique radiation. The existence of a radiation pressure has thus been firmly established.

It would now appear that this result may be generalised: that in wave motion of every description there is a pressure normal to the wave-front equal in value to the energy density. In the case of sound waves, Altberg, working in Lebedew's laboratory, has quantitatively verified this; and Prof. R. W. Wood has constructed a "wind-mill" driven by sound waves.

To return to ether waves. The phenomenon under consideration has opened up several avenues of progress. It is the foundation of a new and important branch of thermodynamic theory—*the thermodynamics of radiation*—with which are associated the names of Bartoli, Boltzmann, Wien and others. It has formed the basis of some very interesting astronomical applications, mainly at the hands of Arrhenius and Poynting. It leads to some considerations on the interaction of matter and ether which are of interest at the present moment, when the foundations of the Newtonian mechanics are in question and the principle of relativity is bidding for the scientific ear.

Interpretation of Radiation Pressure.

§2. The existence of a pressure is an obvious consequence of an emission (or corpuscular) method of propagation of energy. It is of interest to see how the pressure arises in wave propagation.

(i) *Light*, *heat* and *electrical waves* are, on Maxwell's electromagnetic theory, all of the same type. In the plane of the wave-front are tubes of electric and of magnetic force. Such tubes behave as though in a state of longitudinal tension, whilst they exert a lateral repulsion on adjacent tubes of the same sign. These lateral pressures are represented, in terms of the magnetic force H and the electric force F, by the well-known expression $\mu H^2/8\pi$ and $KF^2/8\pi$. They combine to form a resultant pressure which is equal to the energy density in the medium. Maxwell ("Electricity and Magnetism," Vol. II.) deduces his pressure from these considerations, and proceeds to a calculation of the pressure on a square foot of the earth's surface due to strong sunlight, the pressure assigned being the energy in 1 cubic ft. of sunlight.

Sir J. J. Thomson regards the force, when the light is incident on a reflecting surface, in terms of the induced electric currents in the surface. A perfect reflector is a perfect conductor. The alternations of magnetic force cause induced currents confined to the surface layer of the conductor. These currents are in direction perpendicular to the tubes of magnetic force in the incident wave-front. The usual laws of mechanical force on a conductor

Digitized by Google

carrying a current in a magnetic field will apply and the conducting surface will be repelled. When the medium transmits the light the force is reversed after passage over half a wave-length. Integrated over a distance of many wave-lengths, the resultant effect would be zero. The force will thus be a maximum for infinite conductivity, dying down as the conductivity, and therefore reflecting power of the medium falls off.

(ii) *Sound Waves.*—If we consider a mass of air contained in a cylinder in which a piston fits, it is easy to see that the confined air behaves very differently from an ordinary spiral spring. Even if the changes are at constant temperature, the application of Boyle's law shows that the increase of pressure for a given displacement of the piston inwards is appreciably greater than the decrease due to the same movement outwards. Still more must this be the case when the action is adiabatic, when motion inwards causes a rise, motion outwards a fall, of temperature. Thus, in a sound wave in a gas, since the gas pressure rises a little more above the normal in the compression half-period than it falls below in the rarefaction half, there is clearly an average pressure forwards on any surface on which the sound falls. Strictly speaking, the assumption of simple harmonic particle motion here made is not quite justifiable; Lord Rayleigh has shown, however, that in the case of isothermal change the forward pressure does exist in amount equal to the energy density in the wave.

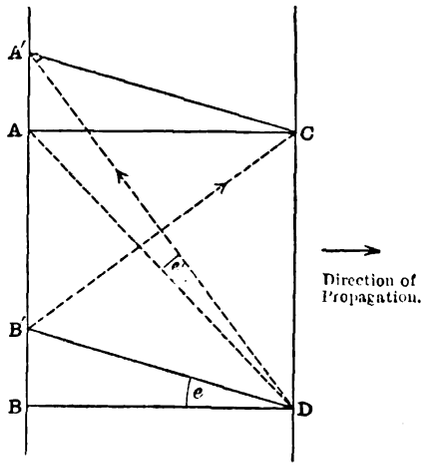

Fig. 1.—Pressure arising in Shear Waves.

(iii) *Transverse Waves in an Elastic Solid.*—Prof. Poynting has indicated a method of interpreting the forward pressure in the case where, for example, energy is being propagated along rotating steel shafting. During shear there is a force of compression along one axis of the shear and an equal force of tension along the second axis, which is perpendicular to the first. But these axes do not make equal angles on either side of the perpendicular to the planes of shear—*i.e.*, with the direction of propagation of the shear. If e denotes the angle of shear, one shear axis, that of compression, is turned by the amount $e/2$ nearer the normal; the other along which there is tension is turned by the same amount away from the normal. The effect is evidently to destroy the exact balance of these forces, yielding a slight excess of forward push over backward pull; and this difference works out to be equal to the energy-density in the shafting. In the diagram (Fig. 1) ABCD represents a section parallel to the direction of propagation. Particles at A and B are displaced to A′ and B′ in the plane of shear, whilst the disturbance is passing over the length AC. The compression axis CB′ makes with CA the angle $\left(45°-\frac{e}{2}\right)$, while the axis of tension DA′ makes the angle $\left(45°+\frac{e}{2}\right)$ with DB. Clearly the resultant is a pressure in the plane through CD in the direction of propagation. Its magnitude proves to be of the value required.

(iv) *Interpretation from the Energy Point of View.*—Larmor has applied the principle of the conservation of energy to the problem, thereby deriving very simply the magnitude of the radiation pressure. This proof, as Poynting has observed, holds for any type of radiation in which the energy density for a given amplitude is proportional to the square of the frequency. This simple law, of course, holds in the case of a single particle of matter moving with simple harmonic motion.

The simplest case to examine is that of a plane-radiating surface emitting plane waves. The surface will experience a pressure of recoil of value equal to the energy density. This may be seen by supposing the surface to move with velocity denoted by v in the direction of propagation of the radiation. Let V denote the wave velocity. The effect of the motion of the source is, in accordance with Doppler's principle, to raise the frequency of the emitted vibrations in the proportion $V/(V-v)$. If, then, E denote the energy density when the source is at rest, the measure of this quantity when the source is moving will be $E \cdot V^2/(V-v)^2$. In one second the source will have moved forward a distance v, and the energy emitted per second per unit area will, therefore, be crowded into the volume $(V-v)$ of the medium, the amount present being thus

$$E \cdot \frac{V^2}{(V-v)^2}(V-v) = E \cdot \frac{V^2}{(V-v)}.$$

When the source is at rest the energy emitted per second is EV. The source thus emits more energy per second when moving than if it were at rest. This implies a back pressure, p, against the source, and we may write

$$p = E \cdot \frac{V^2}{V-v} - EV = E \cdot \frac{Vv}{V-v},$$

which, when $v = 0$ becomes $p = E$.

Experimental Work.

§ 3. Great as the influence of the existence of a light pressure is in extending theory, the order of magnitude of these forces is not such as to make them of sensible importance in terrestrial mechanics. The steps taken by the physicists already named in disentangling these forces from insistent disturbing effects, and submitting them to accurate measurement, are of a high order of interest.

In the case of radiation falling normally on a surface which absorbs it completely, the pressure is equal to the energy per unit volume of the incident radiation. When the surface is totally reflecting, the energy density is doubled by the superposition of the reflected beam upon the incident one, and the pressure is correspondingly doubled. In the former case the pressure caused by full sunlight at the earth's surface amounts to 0·59 milligrams per square metre (or $0·58 \times 10^{-3}$ C.G.S.); for a total reflector it therefore exceeds 1 milligram per square metre. By means of the arc an intensity of perhaps 20 or 40 times that of sunlight can be applied. Such is the order of the forces to be measured.

The methods adopted in the three series of measurements referred to agree in that the light forces were made to act upon delicate vanes set at the end of a horizontal arm, producing a couple which was opposed by the torsional control of a fine suspending fibre.

The arrangements adopted by Lebedew are represented in Figs. 2, 3 and 4.

Two pairs of circular discs of platinum 5 mm. in diameter were mounted, as shown in Fig. 2 (elevation), at the ends of two light rods, these rods being attached perpendicularly to the vertical glass rod HH. The system was suspended by a glass fibre, T, in a glass globe about 20 cm. in diameter. The discs P_1, Q_1 have a thickness of 0·1 mm., and the lower pair, P_2, Q_2, a thickness of 0·02 mm. P_1 and P_2 are polished on both sides, whilst Q_1 and Q_2 are electrolytically coated with platinum black, the depositing current being maintained for times in proportion to the thickness of the plates. M is a mirror used in conjunction with a telescope and scale. The method of illumination of the discs is shown in Fig. 3. Radiation from an electric arc at S falls on a lens, and by the mirrors M and a second lens may be made to converge on either side of the disc A at will, the mirror M being capable of movement to a second position, M′, indicated by the dotted outline.

Digitized by Google

In addition to the light pressure on the disc there are the two forces constituting the gas action—namely, the radiometer effect and that arising from convection currents. By the use of very thin discs of metal the radiometer action was very much reduced, since it depends on a difference of temperature between the two faces of the disc. It is always in the same direction as the light pressure; but by comparison of the deflections obtained successively with the thick and thin discs it may be eliminated in the final calculations.

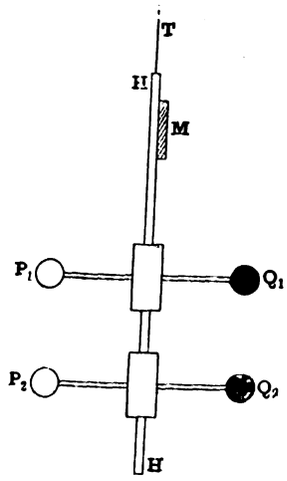

FIG. 2.—SUSPENDED SYSTEM (Lebedew).

The effect of convection was but very small, since the globe was exhausted of air to the utmost extent possible with a Sprengel mercury pump. The direction of the disturbing couple due to convection is, moreover, independent of the side of the disc on to which the beam is directed, the difference of temperature of the two faces being in this respect negligible. The mean of deflections taken with the light, first on one face, then on the other, is thus free from the convection effect.

It is to be observed that the light pressure effect should, according to theory, be practically twice as great for the polished as for the black disc; whilst the rise of temperature in the case of the black disc will be greater than for the polished

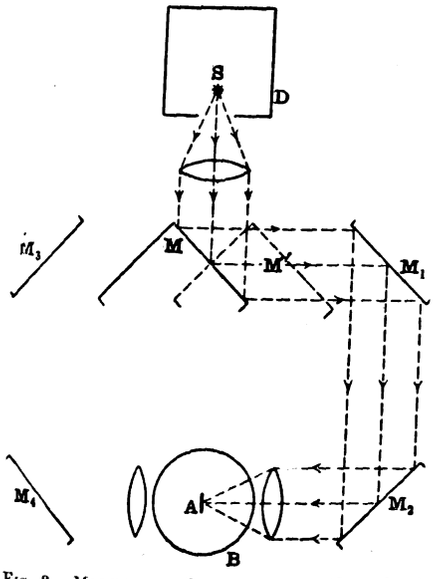

FIG. 3.—METHOD OF ILLUMINATION (Lebedew).

one, and consequently the gas action greater. That the radiometer action was sufficiently annulled was judged from the fact that a polished disc was repelled more strongly than the corresponding blackened one.

The deflections obtained were reduced to the equivalent couples in the usual way, by observation of the times of vibration of the suspended system before and after the addition of a known moment of inertia.

The absolute measure of the intensity of radiation employed was obtained by a simple calorimetric apparatus (*see* Fig. 4). A plate, D, containing an aperture of area equal to that of the discs, was placed in the globe so that the aperture coincided precisely with the position previously occupied by a disc. Behind it is a small copper cube weighing 30 grammes, with one face, C, blackened. In a hole drilled in the cube is embedded the bulb of a thermometer, T, a little mercury being used to ensure conducting contact. The rise of temperature in a given time is obtained when the light is directed on to the cube under the conditions of the main experiments. A simple calculation leads to the required datum. Lebedew was finally able to announce the discovery of a pressure equal, within the limits of error of experiment, to that predicted by Maxwell.

Nichols and Hull's researches involved an exhaustive examination of the nature of gas action. Experiments were made at various pressures of the air surrounding the suspended system. Whilst, as exhaustion proceeds, radiometer action becomes more pronounced, the effect of convection currents is reduced. It is thus possible to pit these disturbing effects against one another. In the apparatus employed by Nichols and Hull a zero resultant effect was found to be most nearly secured when the pressure was about 16 mm. of mercury.

The vanes on which the radiation was received were circular discs of thin glass silvered on one side, the silver film being polished on its exposed side.

The gas action is independent of the face of the disc on which the radiation first falls. The incident rays have already been sifted by the glass walls of the containing vessel, so that in the case where the radiation falls on the unsilvered face of the disc it is transmitted entirely by the glass, and falling on the silver film raises its temperature to the same extent as when the beam is directed first on the silvered face. Thus, when the incident beam meets the silvered face first, the light pressure and the slight outstanding gas action are in the same direction; when the beam falls first on the unsilvered face the light pressure and the gas action are opposed.

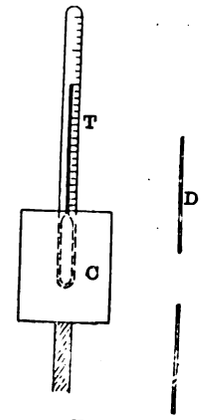

FIG. 4. CALORIMETER (Lebedew).

Furthermore, in order to reduce the gas action to a minimum, the observations were "semi-ballistic." The radiation was allowed to fall upon the vanes for a time (some six seconds) equal to one quarter the period of oscillation of the suspended system, and the throw was observed. The gas action takes a few minutes to develop fully, hence the above procedure.

The authors appear to have secured agreement to within 1 per cent. between the light pressure measured and that deduced from the energy measurements.

A very simple method was subsequently proposed, and carried out by Hull, with the object of eliminating the gas action. It consists in enclosing the vanes within airtight thin-walled glass cells, vane and cell being in rigid connection (*see* Fig. 5). The thin glass walls of the enclosure are practically at the same temperature as the surrounding gas, since,

FIG. 5.—HULL'S SUSPENSION.

as already explained, they do not absorb any of the incident radiation. Forces on the vanes are attended by equal reactions on the walls of the containing cells, so that the couple on the suspended system is nil. This device proved highly successful. The light repulsion was measurable at practically any pressure from that of the atmosphere downwards in the containing vessel. Gas action was reduced to 2 per cent. of the light pressure. With this arrangement the pressure due to light may be comparatively easily demonstrated.

Prof. Poynting has initiated a series of experiments suggested by a fresh point of view of the radiation pressure—namely, that in which the radiation is regarded as a stream of

Digitized by Google

momentum. Not only is *energy* carried by the undulating medium, but also momentum, the amount of the latter in unit volume being obtained by dividing the energy density by the velocity of propagation. When light is incident on matter, whatever momentum the light loses the matter gains, and *vice versâ*. A simple analysis on the basis of the principle of the conservation of momentum shows that at total reflection, and at refraction, the light forces are normal to the surface for all angles of incidence. At reflection the surface is urged in the direction of the incident light, at refraction the force is in the opposite direction—a pull instead of a push—in the case of passage of the light into a denser medium. When absorption takes place the tangential component of the light stream, as well as the normal component, is destroyed; wherefore the surface experiences a tangential force in addition to the normal one.

These consequences have been verified by Prof. Poynting and Dr. Barlow. Two experiments due to them will be adduced. In the first, two discs of glass, one silvered (S) and the other blackened (B), were fixed vertically at the ends of a

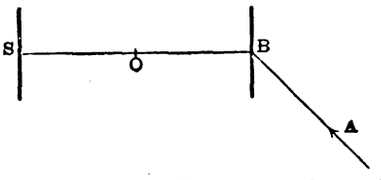

Fig. 6.—Demonstration of Tangential Force (Poynting).

thin horizontal glass rod, the system being hung by a quartz fibre attached at O, as shown in the diagram of Fig. 6. A beam, A, from a Nernst lamp was allowed to fall at an angle of 45 deg. on first one disc then the other. The arrangement is such that normal forces acting uniformly over the discs produce no couple on the system. Radiometric action is thus eliminated—a noteworthy advantage of this disposition of the discs. Any torque observed is, therefore, a measure of the tangential forces present.

The deflection when the stream was directed on B was very much greater than when directed on S. In a particular experiment the torque observed in the former case was 21×10^{-6} cm. dyne, whilst the value calculated from the energy was 22×10^{-6} cm. dyne.

A second experiment, showing the effects at refraction, is indicated in the diagram (in plan) of Fig. 7. Two glass prisms, with refracting angle 34 deg., were mounted at opposite ends of a glass arm 3 cm. long, the system being then hung from a

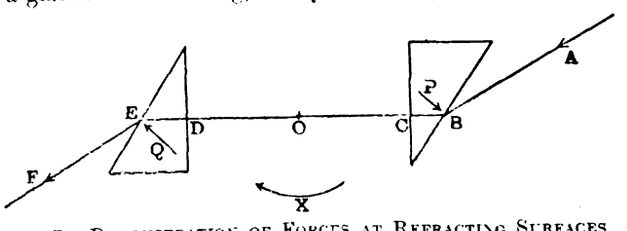

Fig. 7.—Demonstration of Forces at Refracting Surfaces (Poynting).

quartz fibre attached at O. A beam of light, ABCDEF, entered one prism at B, emerging at E from the second prism. The system turned in the direction shown by the arrow X. The forces acting have their points of application at B and E, being normal to the surfaces, and of sign represented by the arrows P and Q. The order of magnitude of the deflections observed was as expected.

Further additions to the list of beautiful experiments on the forces due to light might be made. Simple mention must suffice of a wonderful demonstration by Prof. Lebedew of the pressure on an absorbing gas, a consummation which could hardly have been thought possible in view of the small absorbing power which gases possess.

In a succeeding article it is hoped to put forward an account of the three lines of inquiry which take their origin in the fact of the radiation pressure.

CORRESPONDENCE.

PERMANENT MAGNETS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have been much interested in reading the article on "Some Alloys for Permanent Magnets" in your issue of Aug. 18. Such information is very badly wanted, because those manufacturers who supply permanent magnet steel (and most of it comes from Germany) keep the processes a close trade secret.

It really is surprising what a long time properly made permanent magnets will retain their magnetism. For example, at the South Head lighthouse, Sydney, New South Wales, there are two De Meritens alternators with permanent magnets. They have been in constant use for over 20 years, and, although I made every inquiry possible, I could not find that the magnets had shown any falling-off during that time, and there was certainly no record of their having been changed.

The discovery of self-excitation sets permanent magnets back, but with the advent of internal-combustion engines, especially petrol engines for motor cars, motor cycles, motor boats and for aviation, the demand for magneto-generators has increased enormously. From being more or less a toy, the magneto is now a most important link in the two most modern methods of rapid transit, and that, if nothing else, shows its reliability.

The demand for permanent steel has grown to such an extent, and the prices asked for it are so high, that it is to be hoped that some of the Sheffield people will soon produce a steel equal to, if not better than, Remy and at a much lower price.

One use for which permanent magnets are suited is for small electric motors. We have now arrived at the point when electricity should be exploited for the "million" and not for the luxurious "few"; but so far as small motors are concerned it will never be done at the present ruling prices. One has only to consider what a sovereign or two will buy in the way of a sewing machine, a bicycle or rifle and compare it with what one gets in the way of a motor and starter.

One of the principal items of expense in small motors, and the part which is likely to break down, is the field winding. The wire is very small and at the best is only thinly insulated whilst the number of turns, especially at the higher voltages, is very high. Then, again, if regulation is attempted by means of a shunt resistance the thing is far from robust.

By using permanent magnets the field coil difficulty disappears at once and speed regulation can be effected by merely shunting more or less of the lines of force through an iron keeper. The writer's Patent Specification, No. 24,023 of 1909 ("Improvements in Direct-Current Motors") may be of interest to those who wish to go into the matter further.

It may be said that permanent magnets will not give the required magnetic flux and will not retain it. This is where the researches by Messrs. Burgess & Aston are so useful, for they show that quite high values of magnetic flux can be obtained. Even when field coils are fitted on small motors, the possible magnetic flux is very much lower than what is customarily used in dynamos and large motors. The magnet poles and yoke, &c., are all so near together on quite small motors that there is excessive leakage if the magnetic flux is forced up to much above what is possible with permanent magnets.

Again, as to permanence of the magnetism, the above-mentioned investigations have shown that a few per cent. of some alloy make a remarkable difference to the coercive force. Besides, as I have already mentioned, permanent magnets made over 20 years ago are still doing duty. In any case it is not likely that any small motor will be subjected to a fraction of the vibrations that a magneto has to put up with on a motor car.

I think there is a field for the small output permanent magnet motor, made by the thousand as are magnetos and sewing machines, &c. As for appearance, cast steel

Digitized by Google

permanent magnets should be possible, and possibly it may be found that chilled cast iron may give a sufficiently high flux for the smallest sizes. Such chilled cast-iron can be made into very good permanent magnets. The whole matter strikes me as well worth further investigation.—I am, &c.

Bromley, Aug. 24. E. KILBURN SCOTT.

EFFECT OF ALTERNATING CURRENT ON DRAWN TUNGSTEN WIRE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have noted with interest the editorial in your issue of August 25th on the "Progress of the Metal Filament Lamp," and the abstract of an article by Dr. Monasch on the same subject. In this article and editorial it is stated that "drawn tungsten wires behave with alternating current in the same way as the tantalum filament; the molecular structure changes, and, for practical purposes, with alternating current, this is a very grave defect."

I desire to advise you that this statement is in error so far as it concerns the drawn-wire employed by the British Thomson-Houston Co. in their new drawn-wire Mazda lamps, a description of which appears in the same issue of your paper. This wire is absolutely free from any "off-setting" with alternating current, which is such a characteristic feature of tantalum wire, so that the drawn-wire Mazda lamp gives equally as good life on alternating current as it does on direct current.

We shall be much obliged if you will publish this correction of the statement of Dr. Monasch and your editorial.—We are, &c.,

London, Aug. 29. F. W. Willcox.

A NEW HIGH-FREQUENCY GENERATOR.*

BY PROF. A. LARSEN.

Summary.—A method of generating small high-frequency currents is described, a telephone receiver being connected to a microphone by adjustable air-tubes. The periodicity can be varied from 600 to 1,100 per second.

It is a well-known fact that a telephone will emit a sound when it is connected to a microphone through a transformer, as shown in Fig. 1. The vibration is, however, rather unstable; a slight change

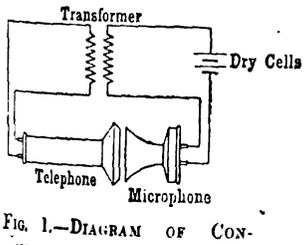

FIG. 1.—DIAGRAM OF CONNECTIONS BETWEEN THE TELEPHONE AND MICROPHONE.

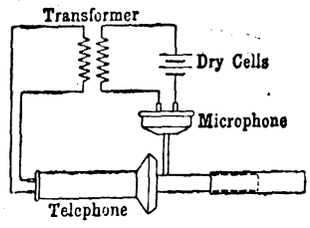

FIG. 2.—DIAGRAM OF A.C. GENERATOR WITH ADJUSTABLE TUBE FOR REGULATING THE FREQUENCY.

in the relative positions alters the pitch of the note considerably. The author had occasion to carry out certain tests with regard to the vibration of the membrane of a telephone receiver, and was surprised to find that these vibrations depend on the columns of air which are set in motion. The idea, therefore, suggested itself that the above-mentioned humming telephone might be controlled by adjusting the volume of air that was set in vibration, and that in this way a simple and cheap form of generator might be made for purposes of measurement. The first form of the apparatus, which was the outcome of this idea, is shown diagrammatically in Fig. 2. An open brass tube is screwed to the mouth of the receiver, and another tube is arranged to slide over the first. A narrow side tube leads, as shown, to the microphone. The microphone is in series with two dry batteries, and acts on the telephone through the medium of an ordinary microphone-transformer. If the open tube is drawn out to a suitable distance, the system is set in vibration, and the frequency can be adjusted within wide limits by altering the length of the tube.

When the frequency was considered as a function of the tube length, and plotted out in the form of a curve, certain peculiarities showed themselves. The curve fell suddenly when the tube length approached a certain definite amount, and then resumed its regular course. This irregularity was at first ascribed to some property of the membranes of the telephone or microphone. Rather thicker membranes were, therefore, substituted for them; the frequency was thereby affected, but the irregularity remained as before, and corresponded to about the same tube lengths as before. The only possible explanation was, therefore, to be found in the action of the air in the hollow space behind the membrane of the telephone. This was found to be the case, for the irregularity disappeared as soon as the space was filled with paraffin oil, and the apparatus in this form was found to be suitable for frequencies of over 1,000 per second. It became evident at once that the air behind the membrane might also be utilised in the working of the apparatus, and this gave rise to the second form of the apparatus shown in Fig. 3. Here on both sides of the receiver sliding tubes of equal lengths are connected up, and the frequency can in this case be varied steadily from 600 to 1,100 per second.

In order to maintain the state of vibration, the forces, exercised through the microphone, and alternately attracting and repelling the membrane of the telephone, must be adjusted to a certain phase. This force is best arranged so that it is one-quarter of a period in front or three-quarters of a period behind the phase of motion of the membrane. Suppose its phase to be other than this. It can then be resolved into two components, of which the one has a phase displacement of a quarter period, and the other has the same phase as the vibration (or it may be the opposite phase). This last component will act as though the air pressure on the membrane had been increased, and in this way the frequency will be somewhat affected.

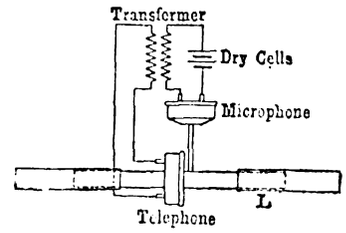

FIG. 3.—A.C. GENERATOR WITH TWO ADJUSTABLE TUBES FOR REGULATING THE FREQUENCY.

The apparatus is intended to be used in connection with the author's "complex compensator," already described in THE ELECTRICIAN. (*See* THE ELECTRICIAN, Vol. LXVI., p. 736.) It is being put on the market by the A.-G. Dansk Telegrafonfabrik of Copenhagen; and while it is cheap, it works well as a generator of small high-frequency currents with frequencies between the limits of 600 and 1,000 per second. The current is best taken from the secondary terminals of the transformer, and then passed through another transformer so as to be reduced to a suitable voltage for measurement purposes. The frequency may at first vary by as much as 1 per cent., but after that it will remain almost entirely constant with small variations amounting to 0·2 per cent. The small sudden variations, which occur quite unavoidably with ordinary high-frequency machines driven by a motor, are quite absent. For measurements on telephone cables the constancy of the frequency, when once adjusted, is of considerable importance; and for all measurements which have to be made outside a laboratory it is very convenient to be able to dispense with the use of accumulators; in the present case it is only necessary to take two dry cells for use in connection with the microphone. The output is, of course, very small, but it is fully sufficient for the purposes in view.

PROF. WALKER'S ADDRESS TO SECTION "B" OF THE BRITISH ASSOCIATION.*

THEORIES OF SOLUTIONS.

Twenty-one years ago the Chemistry Section of the British Association at its meeting in Leeds was the scene of a great discussion on the nature of solutions. To-day, speaking from the honourable position of President of the Section, I conceive I can do no better than indicate the position of the question at the present time. And this appears to me the more appropriate as our science has had this year to mourn the departure of van 't Hoff, the founder of the modern theory of solution, whose name will remain one of the greatest in theoretical chemistry—in time to come, it will, I think, be considered almost the greatest. His ideas are part and parcel of the chemical equipment of every one of us, and we know that whatever form the fundamental conceptions of chemistry may assume, the quantitative idea of osmotic pressure will be to the theory of solution what the quantitative idea of the atom is to chemical composition and properties. For I must emphasise the fact that chemistry is essentially a quantitative science, and no chemical theory, no partial chemical theory even, can be successful unless its character is quantitative.

A general theory of solutions must be applicable to all solutions—to those in which solvent and solute exist in practically mere intermixture, as well to those in which solute and solvent are bound together in what we cannot sharply distinguish from ordinary chemical union. Between these extremes all grades of binding between solvent and solute exist. Herein lies the importance of van 't Hoff's osmotic pressure theory. It applies equally to mixtures of gases, to mixtures of inert liquids, and to mixtures such as those of sulphuric acid and water; and it has the further advantage that so long as the solutions considered are dilute there are simple relations connecting the osmotic pressure with other easily measurable properties of the solutions. It has been unfortunately the custom to oppose the osmotic pressure theory of solution to the hydrate, or more generally the solvate, theory, in which combination between solute and solvent is assumed. The solvate theory is, in the first place, not a general theory, and in the second place it is perfectly compatible with the osmotic pressure theory. It is, in fact, with regard to a general theory of solutions on the same plane as the electrolytic dissociation theory of Arrhenius. This theory of ionisation applies to a certain class of solutions, those, namely, which conduct electricity, and is a welcome and necessary adjunct in accounting for the numerical values of the osmotic pressure found in such solutions. Similarly, the hydrate, or more generally the solvate, theory is applicable only to those solutions in which combination between solvent and solute occurs, and will no doubt in time afford valuable information with regard to the osmotic pressure, especially of concentrated solutions in which the affinity between solvent and solute is most evident. It can tell us nothing about solutions in which one, or both, components is inactive, just as the electrolytic dissociation theory can tell us nothing about solutions which do not conduct electricity.

The great practical advantage bequeathed to chemists by the genius of van 't Hoff is the assimilation of substances in dilute solution to substances in the gaseous state. Here all substances obey the same physical laws, and a secure basis is offered for calculation connecting measurable physical magnitudes, irrespective of the chemical nature of the substances and of the solvents in which they are dissolved, provided only that the solutions are non-electrolytes. If the solutions are electrolytes, the dissociation theory of Arrhenius, developed independently of the osmotic pressure theory of van 't Hoff, gives the necessary complement, and for aqueous solutions offers a simple basis for calculation. Van 't Hoff has given to science the numerically definable conception of osmotic pressure; Arrhenius has contributed the numerically definable conception of coefficient of activity of electrolytes in aqueous solution, or what is now called the degree of ionisation.

Of late there has been a tendency in some thermodynamical quarters to belittle the importance of the conception of osmotic pressure. It is quite true that from the mathematical thermodynamical point of view it may be relegated to a second place, and even dispensed with altogether, for it is thermodynamically related to other magnitudes which can be substituted for it. But it may be questioned if without the conception the cultivators of the thermodynamic method would ever have arrived at the results obtained by van 't Hoff through osmotic pressure. Van 't Hoff was only an amateur of thermodynamics, but the results achieved by him in that field are of lasting importance, and his work and the conception of osmotic pressure have given a great stimulus to the cultivation of thermodynamics to chemistry.

The outstanding practical problem in the domain of electrolytic solutions is to show why the strong electrolytes are not subservient to the same laws as govern weak electrolytes. If we apply the general mass-action law of chemistry to the electrically active and inactive parts of a dissolved substance (the ions and un-ionised molecules) as deduced from the conductivities by the rule of Arrhenius, we find that for a binary substance a certain formula connecting concentration and ionisation should be followed, a formula which we know by the name of Ostwald's dilution law. This law seems to be strictly applicable to solutions of feeble electrolytes, but to solutions of strong electrolytes it is altogether without application. Wherein lies the fundamental difference between these two classes of solutions? Two kinds of explanation may be put forward. First, the ionised proportion may not be given accurately for strong electrolytes by the rule of Arrhenius; or, second, the strong electrolytes do not obey the otherwise general law of active mass, which states that the activity of a substance is proportional to its concentration. The first mode of explanation has been practically abandoned, for other methods of determining ionisation give values for strong electrolytes in sufficient agreement with the values obtained by the method of Arrhenius. The other explanation is that for some reason the law of active mass is, apparently or in reality, not obeyed by some or all of the substances in a solution of a strong electrolyte. An apparent disobedience to the law of mass-action would, for example, be caused by the formation of complexes such as Na_2Cl_2, or Na_2Cl^+ or $NaCl_2^-$ in a solution of sodium chloride. Mere hydration, *e.g.*, the formation of a complex $NaCl, 2H_2O$, would not affect the mass-action law in dilute solution, and the electrolyte would obey the dilution law in solutions of the concentration usually considered. A somewhat similar explanation, which takes into account the properties of the solvent, is that the ionising power of the solvent water undergoes a noticeable change when the concentration of the ions in it increases beyond a certain limit.

I should wish now to draw attention to a point of view which has not, so far as I am aware, been fully considered. To begin with we may put to ourselves the question: Is it the ions in the solution which are abnormal or is it the non-ionised substance? A simple consideration would point at once to it being the non-ionised portion. We have, for example, in acetic acid a substance which behaves normally, so that the ions H^+ and Ac^- as well as the undissociated molecule HAc are normal. Similarly, in ammonium hydroxide the ions NH_4^+ and OH^- as well as the non-ionised NH_3 and NH_4OH all behave normally. When we mix the two solutions there is produced a substance, ammonium acetate, which behaves abnormally. Now, on the assumption that the equilibrium we are dealing with is

$$NH_4^+ + Ac^- \rightleftarrows NH_4Ac,$$

which of these molecular species is abnormal in the relation between its concentration and its activity? Probably not the ions NH_4^+ and Ac^-, because these were found to act normally in the solutions of acetic acid and ammonia. The presumption is rather that the abnormal substance is the undissociated ammonium acetate, for this occurs only in the abnormal acetate solution, and not in the normal acetic acid and ammonia. This view, that it is the non-ionised portion of the electrolyte which exhibits abnormal behaviour and not the ions, has been reached on other grounds by Noyes and others, and I hope in what follows to deduce reasons in its support.

One is apt, because the ions are in general the active constituents of an electrolyte, to lay too much stress on their behaviour in considering the equilibrium in an electrolytic solution. We are justified in attributing the fact that acetic acid is a weak acid, whilst trichloracetic acid is a powerful one, rather to the properties of the un-ionised substances than to the properties of the ions. The divergence of trichloracetic acid from the simple dilution law may similarly be due to an inherent property of the un-ionised acid, a single cause being not improbably at the bottom of both the great tendency to split into ions in water and also the abnormal behaviour towards dilution. However that may be, reasoning goes far to show that the non-ionised portion of the electrolyte is that which is primarily abnormal in its behaviour, the ions acting in every way as normal. The dilution formulæ of Ostwald or of van 't Hoff is essentially equilibrium formulæ. One side of the equilibrium represents the interaction of the ions to form the non-ionised substance, the other side represents the splitting up of the non-ionised substance into ions. To put the whole matter briefly, in the equilibrium between electrolytes agreement will be obtained between theory and experiment whether we use the mass-action law, or an empirical law such as van 't Hoff's dilution formula, provided only that we attribute the abnormality to the non-ionised portion of the electrolyte. Thus

* Abstract of the Address delivered by Prof. J. Walker, D.Sc., F.R.S., at Portsmouth yesterday.

Digitized by Google

we can deduce the ordinary formulæ for hydrolysis or for isohydric solutions as readily for abnormal as for normal electrolytes, and find the most satisfactory agreement with experiment in both cases. By this one simple assumption, then, it is possible to find a basis for calculation with abnormal electrolytes. The problem of *why* certain electrolytes should be normal and others abnormal is, of course, in no way touched by this assumption. That is a matter for further investigation and research.

Another great desideratum of the theory of solutions is to find a general basis for the calculation of hydrates. The present position of the theory of hydrates in solution may perhaps most aptly be compared with the theory of electrolytic dissociation for solvents other than water. That hydrates exist in some aqueous solutions is undoubted, but no general rule or method exists for determining what the hydrates are and in what proportions they exist. Similarly, the theory of electrolytic dissociation applied to other than aqueous solutions affords no general means of determining what the ions are and how great is the degree of ionisation. It is only for aqueous solutions that Arrhenius was able to give a practically realisable definition of degree of ionisation, and it is on this definition that the whole effective work on aqueous electrolytes is based; and until some general practically applicable principle of a similar character is attained for hydrates, the work done on that subject, however interesting and important it may be in itself, must necessarily be of an isolated character.

Arrhenius did not originate the doctrine of electrolytic dissociation or free ions: that was enunciated in 1857 by Clausius, and remained relatively barren. What he did was to introduce measurable quantities into the doctrine and to show its simple quantitative applicability to aqueous solutions; immediately it became fertile. And as soon as a simple quantitative principle is developed for hydrates in solution, that doctrine will become fertile also.

It is surely now time that all the irrelevant and intemperate things that have been said and written by supporters of the osmotic pressure and electrolytic dissociation theories on the one hand, and by those of the hydrate theory on the other, should be forgotten. Far from being irreconcilable, the theories are complementary, and workers may, each according to his proclivity, pursue a useful course in following either. One type of mind finds satisfaction in using a handy tool to obtain practical results; another delights only in probing the ultimate nature of the material with which he works. For the progress of science both types are necessary- the man who determines exact atomic weights as well as the man who speculates upon the nature of the atoms. That the want of knowledge as to what the exact nature and mechanism of osmotic pressure is, should prevent accurate experimental work being done on it, or interfere with its use in theoretical reasoning, is equally ridiculous with the proposition that because in the theory of osmotic pressure we have a good quantitative tool for the investigation of solutions, therefore we should abandon altogether the problem of its nature.

The fundamental ideas of a science are the gift to that science of the few great masters; the many journeymen investigators may be trusted to utilise them according to their abilities. Having once given his great principles to the world, van 't Hoff remained practically a spectator of their development; but by his single act he provided generations of chemists with useful and profitable fields for their labour.

THE OSRAM LAMP AND ITS APPLICATIONS.*

BY H. REMANÉ.

My object in this Paper will be to call your attention to several directions in which the Osram lamp can be used with special advantage, to explain these directions and the results which have been obtained in them. I wish also to explain one or two points which are not quite clear regarding the uses and possible uses of the Osram lamp. You must not forget that we manufacturers set great value on the experience obtained in practice with our lamps, as we cannot get the same variety of the conditions during test as is obtained in practice.

In order to get some reliable information on this question, the Deutsche Gasgluhlicht A.G. sent inquiries to about 1,600 electricity supply authorities in towns and villages, asking whether Osram lamps were used for street lighting, and what were their candle-powers. At the time that the material for this lecture was got together 450 replies † had come to hand, which showed that 185 towns were using Osrams for street lighting. In these places 15,180 Osram lamps are used with a total of 743,000 c.p., of which 67 per cent. are for 220 volts. Lamps used for street lighting are tabulated according to candle-power as follows:—

C.P. ...	16	25	32	40	50	70	100	200	300	400	600	1,000
No.	636	3,319	6,615	695	20,325	285	1,379	135	81	113	56	5
Per cent.	1·9	10·0	20·0	2·1	60·0	0·8	4·0	0·4	0·2	0·3	0·1	—

In the following table the Osram lamps used in street lighting are tabulated according to candle-power:—

C.P. ...	16	25	32	40	50	70	100	200	300	400	600	1,000
No. ...	305	1,714	2,213	639	9,354	285	486	57	36	78	15	1
Per cent.	2·0	11·3	14·6	4·2	61·5	1·9	3·2	0·3	0·2	0·5	0·1	—

The majority of Osram lamps (61·5 per cent.) are 50 c.p., and it is satisfactory to note that very few, actually only 2 per cent. of the Osrams used in street lighting, are of 16 c.p. These are evidently lamps in unimportant streets or emergency lights. It might have been expected that a large number of 100 c.p. lamps would be used for street lighting. That this is not the case may be due to several causes, the first and principal one undoubtedly being that the former 16 c.p. glow lamps were simply replaced by Osrams of the same candle-power so that the lighting system should not be any further loaded up. Secondly, incandescent gas lighting is still predominant in the larger towns. It is well known that in Germany at least many of the smaller towns have for years owned their own gasworks, and that with the advent of the gas mantle many other gasworks were laid out in very small towns.

The streets in such towns are generally lighted by gas from the town gasworks. From this we see that the largest towns mostly use gas lighting, and that only small and medium-sized towns and especially small villages have electric street lighting. It is, of course, clear that the demand for light in small villages is not great. In such villages 50 c.p. lamps are used, but greatly improved lighting could be obtained by using lamps of a higher candle-power. The outlook for electric lighting in future is more favourable, especially in connection with the suburbs of rapidly growing towns.

Of the towns which use a large number of Osrams in addition to their gas lighting, Dortmund, with 1,000 Osrams of 50 c.p., and Strassburg, with 3,000 lamps of 32 c.p. and 50 c.p., may be mentioned. In large towns sometimes special conditions cause extensions of the street lighting. For example, in Breslau the boulevards, which are 15 km. (10 miles) in length, are lighted with Osram lamps because the leakage from the gas pipes interferes with the flowers and shrubs. In Breslau 285 70 c.p. and two 200 c.p. lamps are used for boulevard lighting.

Looking at the lamp from the commercial point of view, it is assumed that in a street-lighting scheme carbon filament lamps of 16 c.p. and 25 c.p. have been hitherto used costing 35 pf. (4d.) each. The life of these lamps is taken at 1,000 hours, and the current at 12 pf. (1·2d.) per lamp of 4-watts per candle-power. Taking the efficiency of the 110-volt Osram at 1·1 watt per candle-power and the 220-volt at 1·25 per candle-power, and taking the life of the Osram lamp at the rather low figure of 1,000 hours, and the nett price for the 110-volt lamp at M.1·40 (1s. 5d.), and that of the 220-volt at M.2·30 (2s. 4d.), the following figures for a 2,000 hours run will be obtained:

1. 10 Osrams, 16 c.p.,	Current...	M.42·24	£2	2	3
	Renewals	M.28·00	1	8	0
		M.70·24	£3	10	3
2. 10 Carbon Filament, 16 c.p.,	Current...	M.124·80	£6	4	10
	Renewals	M.7·00	0	7	0
		M.131·80	£6	11	10
3. 10 Osrams, 25 c.p. 220 volts,	Current...	M.74·40	£3	14	5
	Renewals	M.46·00	2	6	0
		M.120·40	£6	0	5
4. 10 Carbon Filament 25 c.p.	Current ...	M.192·00	£9	12	0
	Renewals	M.7·00	0	7	0
		M.199·00	£9	19	0

From the above figures it will be seen that Osram lamps cost so much less than carbon filament lamps that a saving can be made even when carbon filament lamps are replaced by Osrams of double the candle power. For lighting large squares and streets the Osram does not, of course, enter into competition with carbon filament lamps, but Osrams from 100 c.p. to 1,000 c.p. compete with small and medium sized arc lamps.

When I gave a lecture at a conference of German electrical engineers in Erfurt two years ago on the possibility of replacing arc lamps with high candle-power Osram lamps, doubts were expressed whether high candle-power Osrams were really as economical as my figures represented them to be, and it was contended that high candle metal

* Abstract of a Paper read before the Schweizerische Elektrotechnische Verein.

† Up to the time of printing 1,290 replies were received, showing that Osrams are employed in 484 localities. The total number in use is 33,643, with a total of 1,640,000 H.K., about 50 per cent. of the lamps working on 220 volts.

Digitized by Google

filament lamps could never replace arc lamps. Time has proved that these doubts were not justified, and were I to give you figures of the number of high candle-power lamps which have been used since that time you would be astonished. For business reasons it is, however, out of the question for me to give such figures.

In order to give some idea of the results obtained by replacing arc lamps by high candle-power Osrams, I have taken railway installations as examples, owing to the fact that such installations are very compact and suitable for obtaining such data. The Prussian Railway department, which generally wires its own premises, has changed the lighting of many of its railway stations, and whenever it has been considered suitable or likely to be a change for the better has replaced arc lamps. The railway department hold that, apart from the question of economy, better distribution of light can be obtained than with arc lamps, and that as the number of points is greater when Osrams are used, great differences of light and shade such as exist with arc lamps are avoided.

In addition to this, the switches can be arranged in such a manner that lamps can be turned on or off as required. With arc lighting this is not the case, as railway stations are generally lighted with a relatively small number of arc lamps whose candle-power and current consumption are large.

I will give a few data on railway station installations, and especially on the lighting of the Stadtbahnhof Charlottenburg and the Erfurt main line stations.

At the Charlottenburg station the entrances and platforms were lighted by 36 12-ampere alternating-current arc lamps. These were replaced by 86 100 c.p. Osram and four 200 c.p. Osram lamps, the latter high candle-power lamps being erected outside the station and in the booking office. Owing to the larger number of points at which Osrams are installed, the distribution of light shows an enormous improvement.

In order to do away with the carbon filament lamps in front of the train indicator board the two Osrams nearest the indicator are brought about a yard out of line with the other lamps. This secures better lighting of the boards. The saving in current amounts to five units per hour, in addition to which the costs of carbons, maintenance, repairs and attendance are also saved, so that a total saving of M.3,000 (£150) per year has been effected in this railway station. Owing to the fact that there is traffic through the station until a very late hour, it is not possible to make very much use of the advantage of extinguishing part of the lights.

The lamps in this station have lasted very well, and no lamp has become defective due to shaking or other mechanical influence. Lamps under the platforms are hung on cords 1 metre (3·3 ft.) long. They carry no outer globe, but are furnished with enamelled reflectors, and are hung at a height of 4 metres (13·2 ft.). The working pressure is 120 volts, and the installation is connected with the alternating-current network of the Charlottenburg electricity works. The average life of the lamps is 2,000 hours.

At the Erfurt railway station a total of 192 arc lamps were installed, of which the 91 that lighted the main entrance platforms, stores, generating station, goods department and engine shops have been replaced by Osram lamps. The arc lamps which were replaced had the following current consumptions: 3 at 10 amps., 84 at 6 amps., 4 at 4 amps. The lamps were connected in 22 separate series circuits of 23 and four lamps, and had a total consumption of 32·12 kw. The 91 arc lamps in question were replaced by Osrams as below: 89 at 50 c.p., 70 at 100 c.p., 20 at 200 c.p., 1 at 400 c.p. All these lamps are for 220 volts and consume a total of 16 kw. The saving effected was, therefore, 16·12 kw., or about 50 per cent. The total candle-power of the arc lamps was about 28,000, while that of the Osram is only 15,850. One would imagine from these figures that the illumination was considerably less and not so good as before. Actually quite the contrary is the case, as owing to the larger number of points and to the fact that it was possible to hang the lamps lower than would have been possible with arc lamps a much more even distribution of light has been obtained.

The switches controlling the different lamps on the platforms, staircases, &c., are all fixed on a central control board in charge of an attendant who operates them according to the instructions he receives. When a platform is empty a large proportion of the lamps is turned out, and before the platform gates are opened to the public the attendant again switches the lamps on, extinguishing them after the departure of the train. On the platforms and in the sheds the lamps are installed as in the Charlottenburg station. For lighting the goods department lamps are hung on span wires fastened to poles. The current carrying wires are arranged at the sides of the span wire.

That Osram lamps are suitable for use in places where there is vibration is also demonstrated by the experience gained in the Grafin Laura Colliery, near Konigshütte. In the machine rooms and surface workings 32 c.p., 50 c.p., and 100 c.p. 100-volt Osrams are in use. In the underground workings where the lamps hang low small transformers are connected with the main power cables. These transformers formerly each fed 10 carbon filament lamps of 16 c.p., the pressure being 130 volts. These lamps have been replaced by 30 Osrams of 16 c.p. at 70 volts. These lamps are similar to the 25 c.p. 110-volt or the 32 c.p. 220-volt types. About 400 of these lamps are in use altogether, and in spite of the fact that many of them are wilfully smashed an average life of 1,700 hours is obtained. Lives of 3,000 or 4,000 hours are by no means rare with the 100 c.p. lamps. Lately 16 c.p. 135-volt lamps have been successfully used the life of which averages 1,200 hours. When one takes into account the enormous amount of vibration to which lamps are exposed in colliery work and in places which are exposed, it is clear that the extreme sensitiveness which is attributed to one-watt lamps in general has very little effect upon their life.

THE TREATMENT OF SULPHATED STORAGE CELLS.*

BY G. A. PERLEY.

A few very unsatisfactory methods of removing the sulphate have been suggested, including scraping with a wire brush, prolonged charging at a low rate which, though ultimately successful, is very expensive, and charging at a high rate which decreases the capacity of the cell.

The author made a number of tests of chemical methods on 12 badly sulphated cells with five plates per cell, and a rated capacity of forty ampere-hours. They had hastily been put out of commission, the acid not being washed out of the pores of the plates. The general methods employed were chemical reduction, electrolytic deposition and reduction, and solvent action. In the first different mixtures of ferrous oxide and caustic soda both hot and cold were tried without success. Bourtraeger's zinc and hydrochloric acid method was next studied. Using 25 per cent. hydrochloric acid it was found complete reduction took place, but weaker acid down to a 10 per cent. solution gave splendid results, though under the best conditions this method only partially cures the sulphating of a spongy lead plate.

Under the second heading lead was deposited under varying conditions from plumbite, fluosilicate, acetate and perchlorate solutions. The deposition was always accompanied by great shedding of the lead sulphate, and the method was therefore ruled out as unsatisfactory.

In the third heading solvents for the lead sulphate such as sodium acetate and sodium tartrate were used without satisfactory results. But during some experiments with ferrous hydroxide in which an excess of sodium hydroxide was used, it was noticed that where the sodium hydroxide came in simultaneous contact with lead and lead sulphate crystals of lead were deposited. One of the sulphated grids was immersed in a solution containing 500 gms. of caustic soda per litre. The sulphate completely disappeared, lead being deposited after an intermediate formation of yellow salt. A concentration of 65 gms. of caustic soda per litre was found to be best.

Since sodium hydroxide has such an effect on lead sulphate when the latter is in contact with metallic lead, attempts were accordingly made to apply this economically in the case of the sulphated storage cell. If a sodium sulphate solution is electrolysed between two sulphated lead grids, the action of the current would tend to form caustic soda at the cathode. The cathode would then react with the caustic soda just as in the experiments previously described. In fact, the reduction of the lead sulphate should be extremely efficient, because the caustic soda would be formed just where it was needed, in the pores of the grid.

At the anode we should expect to get a more efficient oxidation of the lead sulphate to lead peroxide with a sodium sulphate solution than with a sulphuric acid solution. The potential of oxidising agents is higher in a strongly acid solution than in a neutral or alkaline one, and consequently it is easier to oxidise a substance to a higher stage of oxidation, other things being equal, in an alkaline or slightly acid solution than in a strongly acid one. It ought therefore to be possible to regenerate both plates of the battery simultaneously.

Varying concentrations of sodium sulphate were tried and it was found that the best results were obtained with a concentration of 45 gms. per litre.

Before applying these results in the final tests, some experiments were made with caustic soda and sodium carbonate solutions. The electrolysis of a sodium hydroxide solution should give the maximum

* Abstract of an article in the "Journal of Physical Chemistry."

Digitized by Google

reduction at the cathode and maximum oxidation at the anode. The difficulty is that it is too efficient. Varying concentrations of sodium hydroxide were tried but the reduction is usually so rapid that grids were formed which began to shed after a little service. The manipulation or control of this solution is not easy unless one has had a great deal of practice. While a sodium hydroxide solution can be made to give good results, it is not so satisfactory as a sodium sulphate solution. Varying concentrations of sodium carbonate were also tested. The results are similar to those with the caustic solutions and for the same reasons.

The experiments with the home-made grids indicated that a concentration of about 45 gms. anhydrous sodium sulphate per litre should be the best; but the difference between temporary grids and the commercial ones was so great that it was not felt at all certain that it was safe to reason from one to the other. Some actual runs were therefore made at various concentrations. In order to obtain a comparison, one cell was charged and discharged a great many times at the normal rate with sulphuric acid as the electrolyte.

While it might be considered rather a feat to bring the cell from zero capacity to nearly 70 per cent. of its initial capacity, the run was not really satisfactory. The cell was in very poor condition after this treatment, as the active material began to disintegrate and to shed. Another cell of the same type was filled with sodium sulphate solution and charged at the normal rate until the reduction was complete. This took about 60 hours. Two lead dummies were placed in the container so that the end plates should be reduced rapidly.

A similar run was made with sodium carbonate as electrolyte instead of sodium sulphate. The reduction required about one-third the number of the ampere-hours that the sodium sulphate solution did, but this apparent advantage is much more than counterbalanced by the deposit being too dense and by the excessive shedding. Only about 53 per cent. of the normal capacity could be obtained. To test the effect of concentration of sodium sulphate, runs were made with a saturated solution and with a solution containing about 91 gms. hydrated sodium sulphate (equivalent to 40 gms. anhydrous salt) per litre.

These cells have been giving these high percentage capacities even since then, so there is no chance for error in regard to the facts. It is of course impossible to say whether these two cells were originally better than the other two cells of the same lot or whether there was some difference in the amount that they were used before they were allowed to spoil. All the plates in all the cells were covered with an apparently uniform shell of white sulphate, and the important thing is that they can be brought back into such good condition. It would not be safe to conclude from the two experiments that the dilute sodium sulphate worked any better than the concentrated solution. About 30 per cent. more ampere-hours were necessary to produce complete reduction in the dilute solution than in the concentrated one and this difference is unquestionably a real one. So far as can be judged, the concentration of the solution is important only to the extent that the reduction takes place more rapidily in the concentrated solution than in the dilute one. The tests so far had all been on cells which had become sulphated under rather unusual conditions. The authors have therefore tested two other wrecks on which they were able to lay their hands. The first was an old and badly buckled cell which was rescued literally from the scrap heap.

This condemned cell was restored so as to give 80 per cent. of its original capacity. Considering the condition it was in, this was as much as anybody could hope for. Another cell was only partially sulphated over the surface but had been allowed to stand discharged for a long time.

Although this cell was apparently in poor condition, it was restored practically to its original state. These illustrations suffice to show the general applicability of the method. When one starts with a battery in commission, the acid should be siphoned off and the solution of sodium sulphate run in. It is desirable, but not necessary, to place dummy plates outside the end plates. The cell can then be charged at the normal rate until the sulphate is entirely reduced. This can be determined by the eye; but if that is inconvenient a charge of 60 hours will probably be satisfactory. The sodium sulphate should then be siphoned off and the grids washed once with water. The amount of sodium sulphate remaining in the plates will have a beneficial rather than a deleterious effect. If the water is then drawn off and the normal battery acid run in, the battery should be as good as new, always supposing that the only damage is due to sulphating. In the authors' tests the current efficiency was only about 80 per cent. which is probably lower than it was when the cell was new, though they have no data on that point.

The cost of restoring a cell is low. For the small 40 ampere-hour cells which have been studied, it has taken less than a kilowatt-hour to bring them back to good condition. That means not more than 5d. per cell for electrical energy. Sodium sulphate is cheap and can of course be used over and over again. While good results can be obtained with almost any concentration of sodium sulphate, the time necessary for reduction is increased when the solution is relatively dilute. On the other hand a saturated solution is objectionable owing to the possible crystallisation. An arbitrary concentration of 200 gms. $Na_2SO_4 \cdot 10\,H_2O$ per litre is therefore recommended. The process as outlined is very efficient and has the further advantage that it introduces no deleterious substances into the cell. Of course, it is absolutely essential that the sodium sulphate shall be pure. The ordinary sodium sulphate always contains chloride. With chlorine in the cell the destruction of the plates is only a matter of time and not of very long time at that.

If the time involved is excessive, as it is likely to be in the case of badly sulphated cells, the cost of time and of electrical energy will exceed the cost of handling. It would be a mistake to make any hard-and-fast rule as to which method to employ; but it seems probable that a prolonged over-charge at half rate in the regular battery acid will suffice for cells which are not badly sulphated. For extreme cases of sulphating the sodium-sulphate method is unquestionably the only one which can be used. A special series of tests would be necessary to determine the relative merits of the two methods for intermediate cases. The general results of this paper are as follows: (1) A badly sulphated cell can be restored by charging at the normal rate in a sodium-sulphate solution. (2) It is desirable, but not necessary, to use leaf dummies outside the end plates. (3) A concentration of about 200 gms. $Na_2SO_4 \cdot 10\,H_2O$ per litre is recommended but the concentration can be varied within very wide limits. (4) It is essential to the life of the cell that the sodium sulphate should meet the requirements as to purity which are laid down for battery acid. (5) A very badly sulphated cell can be restored by about 60 hours charge at normal rate. (6) The cost of electrical energy to restore a 40 ampere-hour cell should not exceed 5d. (7) Since sodium sulphate is not deleterious to the cell, it is not necessary that the sulphate solution should be washed completely out of the pores of the plates. (8) It has been stated by others that a cell can be restored by charging a half of the normal rate for a long time in the regular battery acid. It seems probable that the time and electrical energy required would be excessive in the case of very badly sulphated cells.

THE MAGICIAN DYNAMO FOR CAR LIGHTING.

The problem of securing a satisfactory system of motor-car lighting is by no means a new one, and various devices have been introduced from time to time in order to deal with it. One of the chief difficulties to be overcome is the inevitable speed variation of the engine and, therefore, of the dynamo. Of course, the simplest electrical method is to refrain from using a dynamo at all and merely to put in accumulators which can be charged at intervals. The drawbacks of this method are obvious, and the suggestion is hardly practical, at all events so far as vehicles such as the taxi-cab are concerned; for anything above a low efficiency a dynamo must be used.

An ingenious method of overcoming the speed variation difficulty has been adopted in the "Magician" dynamo. The machine consists of a shunt-wound generator whose armature can be driven by the car engine by any convenient method. The special feature of the machine is that its field magnets are capable of rotation through a fraction of a whole revolution. Moreover, the brushes are attached to the field magnets so that they also rotate at the same time. The commutator is L-shaped in section, the brushes being in contact with the horizontal portion. Pressing against the vertical portion is a third brush which is connected to one end of the shunt winding, the other end being connected to one of the first-mentioned brushes. It is obvious that the E.M.F. generated by the dynamo will now depend not only on the speed but also on the position of what may be called the third brush with relation to the others, since the magnitude of the exciting current depends on this position. Attached to the fixed framework is a C spring of ribbon steel (*a* in Fig. 1). This carries a copper contact piece of Δ section and about an inch long (*b*). Attached to the framework of the field magnets is a grooved roller (*c*), whose two halves are, however, insulated from each other in a direction perpendicular to their axes. Hence, when the field magnets move so as to bring the roller into contact with the Δ-shaped copper the two halves are connected together electrically, and the device, therefore, acts as an automatic switch. This switch is in series with the main circuit. If the machine is at rest, the lamps are supplied by the accumulators alone, because normally the automatic switch is open. Directly it is started the fields are excited, and there exists a tendency for them to be dragged round with the armature owing to the magnetic torque. They are, however, prevented from moving at once by a spring. Ultimately, the torque exceeds the tension of

Digitized by Google

the spring, and the magnets move round through a small angle, closing the automatic switch. It will be observed that the instant when this occurs depends upon the value of the torque; this latter depends upon the strength of the magnetic field, and consequently upon the position of the third brush. Hence, by adjusting the position of this brush the speed and E.M.F. at which the dynamo shall be cut in or out can be nicely determined. The third brush, it may be mentioned, is carried on a clamping sheave. If, now, the speed increases, the tendency is for the E.M.F. to rise; this increases the field current, and thereby raises the torque. The result is that the field magnets move a little further round, thus altering the relative posi-

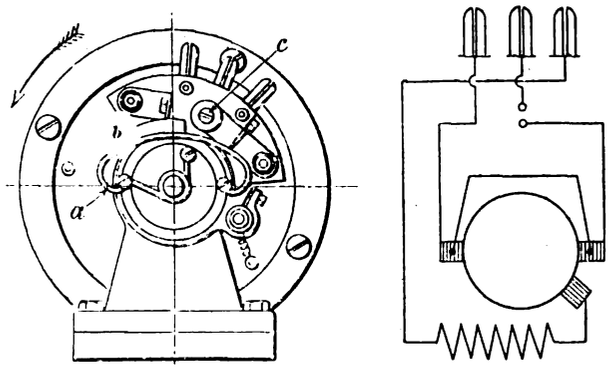

FIG. 1.—GENERAL ARRANGEMENT OF DYNAMO.

tions of the two field brushes, thereby decreasing the difference of potential across the field, reducing the excitation and bringing the E.M.F. back again to its original value. In this way the E.M.F. can be kept constant over a very large speed range. In an actual demonstration which we witnessed the dynamo cut in at 800 revs. per min., and from that speed to 2,100 revs. per min. there was not more than a 5 per cent. variation as indicated by the voltmeter, the lamps and accumulators being in parallel. Directly the speed fell to 800 revolutions again the dynamo cut out automatically, thus avoiding any discharge from the cells through the armature fields.

The behaviour of the machine when short-circuited, or when con-

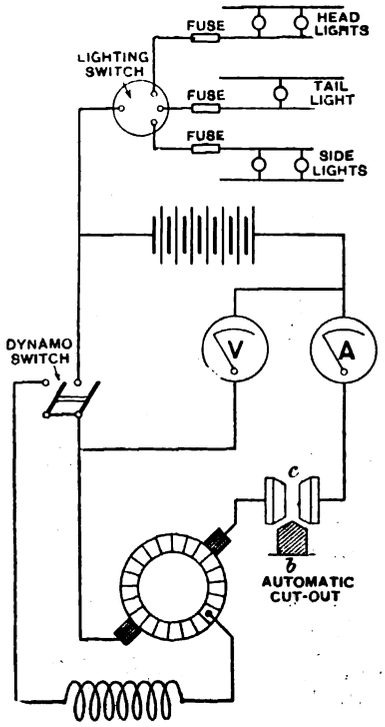

FIG. 2.—DIAGRAM OF CONNECTIONS.

nected up to the cells the wrong way, is particularly interesting. When short-circuited the fields are rocked back by the spring and the automatic cut-out opened; this allows the field to build up again, the magnets are once more dragged round and the dynamo cut in. If the short-circuit still exists this operation is repeated. The result is a violent knocking noise as the magnets oscillate backwards and forwards, and however ignorant a man might be he could not remain unaware that something was wrong.

If the dynamo is connected wrongly to the cells the magnets rock back, and thereby cut the dynamo out. Almost immediately, however, the direction of the E.M.F. in the armature is reversed, the field builds up and the machine is cut in again, this time, of course, with opposite polarity. It would, therefore, seem that the system is not only self-regulating, but also foolproof. Fig. 2 is a diagram of connections.

The "Magician" dynamo is supplied by United Motor Industries (Ltd.), 45-46, Poland-street, London, W.

THE SCIENCE AND OTHER SECTIONS AT SHEPHERD'S BUSH EXHIBITION.

The Science Section, to which we referred in our issue of May 19th, in connection with the opening of the Coronation Exhibition at Shepherd's Bush, we regret to find has not come up to expectations. Demonstrations of electrical apparatus are being given three times daily, at noon, 3 p.m. and 6 p.m., but do not attract a great deal of attention, being of too technical a nature to be understood by the average audience. We must confess, also, that the exhibits of apparatus are somewhat disappointing.

As regards the demonstrations, three methods of ascertaining the temperature in a furnace are shown, viz., a thermo-junction in the furnace, Féry's spiral pyrometer, and the ordinary radiation pyrometer. The stroboscopic method of ascertaining the speed of a revolving shaft by means of a vibrating tuning fork is also demonstrated, whilst Dr. Herbert Smith's refractometer and some apparatus for showing induced reflected waves in a conductor complete the list of apparatus shown in operation. Other experimental apparatus had been promised, but is not now likely to arrive.

The two Marconi stations, one equipped with typical land apparatus and the other for marine work, have aroused much interest, as visitors can witness the process of sending messages between the two stations, which are situated at the ends of one of the halls in the gallery from Uxbridge-road to Wood-lane.

Mention was made in our previous article of some of the electrical apparatus that is to be seen, and little need be added to what we then said. It may, however, be of interest to draw attention to the historic apparatus which has been loaned by King's College. This comprises lodestone used by Faraday, experimental coils of Henry, Wheatstone's rotating mirrors for measuring the velocity of electric waves along conductors, his electromagnetic chronograph and one of his resistance boxes, the original Wheatstone bridge, Dr. John Hopkinson's earliest form of electricity supply meter, one of Clerk Maxwell's models, and the original battery of Daniell.

Messrs. A. C. Cossor exhibit a number of vacuum tubes to illustrate the evolution of the present heavy-discharge X-ray tube from a Crooke's tube; whilst apparatus to illustrate the development of electric valves for rectifying high-tension alternating currents is shown by Sir Oliver Lodge, F.R.S.

Adjacent to the Science Section, the London County Council exhibit one of their electric cars and a section of the conduit. A model is also shown of the slot grip brake used on the Highgate Hill section of the tramway system; in this brake two blocks operate respectively downwards and upwards against the upper and lower surfaces of the special conduit slot rails. The blocks are operated by a helical cam. We also noticed various types of American ploughs.

Attention may be called to the large display which the Gas Companies' Joint Exhibition Committee are making. Much more space has been taken than in previous years, and prominence is given to the various domestic and commercial uses of gas. Visitors, however, are not able to ascertain the effects of a number of gas burners on the atmosphere of a room, since the stand was not enclosed by walls. We noticed that portable gas fittings on the tables, &c., are much in evidence, whilst a special feature is also being made of switches for controlling the lights from a distance. The "Telephos" system (in which a dry cell is used for ignition purposes) and a pneumatic system (in which a special pipe of small bore is installed and the control is by air pressure) are shown. The attempt in the latter system to imitate the popular tumbler switch of electric lighting is proof that gas consumers appreciate the convenience of an electrical installation. Gas fires and gas cookers are, of course, to the fore.

The gas people also have a large display to illustrate the industrial uses of gas. Thus, laundry operations provide an opportunity for bringing gas irons to the notice of the public. A placard near a gas engine which drives some shafting states that gas is the cheapest power for generating electricity for country houses, business premises, theatres, hotels, &c. This is perhaps an admission that the gas industry is giving up hope of ousting electricity.

We regret that the electric supply industry have not a counter-blast to the gas companies' display, but perhaps the electric supply authorities are reserving their energies for the forthcoming Olympia Exhibition.

COMMERCIAL AND INDUSTRIAL SECTION.

MUNICIPAL, FOREIGN & GENERAL NOTES.

BRITISH NOTES.

Bacup.—The Municipal electricity supply undertaking was inaugurated last week. Electric current in bulk is obtained from Rawtenstall Corporation.

Bangor.—An unopposed inquiry was held last week into the Council's application for sanction to a loan of £2,000 for additional generating plant and mains extensions.

The town clerk (Mr. H. W. Rowland) and the borough electrical engineer (Mr. Price F. White) gave evidence in support of the application. Mr. White supplied details of the capacity of the existing machinery and of the growing demand for current in the town.

Buxton.—Application has been made for sanction to borrow £1,000 for mains, &c.

Census of Production.—The Board of Trade have issued a Blue Book dealing with the census of production for 1907.

The gross output (selling value, or value of work done) in the United Kingdom during 1907 was £1,757,000,000, cost of materials used £1,019,000,000, and work given out (amount paid to other firms) £26,000,000. The net output was £712,000,000, and the average number of persons employed (excluding outworkers) was 6,936,000. In addition there were about 100,000 outworkers, and the total number of persons employed on the work covered by the census amounts to about 7,000,000. The following table gives the details for several industries :—

	Output. Gross.	Net.	No. of employés.
Building trades	£87,967,000	£42,954,000	513,961
Gas undertakings (public authorities)	10,769,000	5,732,000	28,585
Gas companies	20,838,000	11,546,000	54,946
Electricity undertakings (public authorities)	5,721,000	3,572,000	14,119
Electricity supply companies	3,182,000	1,996,000	8,499

The total gross output of these industries (including slate, limestone and iron quarries, waterworks, and miscellaneous factories and workshops) was £156,615,000; cost of material used was £63,236,000; work given out to other firms £6,498,000, leaving net output £86,881,000. The total number of persons employed in such industries was 780,747. £26,451,657 represents the gross and £14,356,397 the net output of local authorities in the British Isles, canal, dock, &c., companies, tramway and light railway companies, several Government departments, and the National Telephone Co., which together employed 219,361 persons. The net output of the Post Office telegraph and telephone undertakings was £954,819, and of the National Telephone Co. £510,229, which employed respectively 10,171 and 7,028 persons.

Mr. G. R. Askwith points out in the preface to the Census, that "not only does this, the first census under the Census of Production Act, 1906, show for the first time the relative and absolute mangitudes of all the various industries coming within its scope, but that, when subsequent censuses have been taken, the results of the series will afford the means for measuring the development of the manufacturing and extractive industries of the United Kingdom."

The total quantity of electricity generated by companies and public authorities (exclusive of that generated for their own use by industrial and commercial establishments and by railway and tramway companies) amounted to 1,430,069,000 units. Further, 174,607,000 units were generated by railway companies and 54,743,000 units by tramway and light railway companies for their own purposes.

Association of Chambers of Commerce.—The autumn meeting of this Association is being held in Dublin this week, and many commercial and industrial subjects were dealt with.

Strikes.—A resolution on strikes and intimidation by workers was submitted by the Leeds Chamber on Tuesday. The Hon. R. Beckett, who moved the resolution, said they could concede to anybody the right to strike, but where they quarrelled with him was as to the methods, once a strike was in progress, which led to violence, intimidation and a general breaking of the law. Acts were perpetrated under sec. 2 of the Trades Disputes Act of 1906 which that clause never contemplated. They had there a machinery under which licence and riot had stalked unchecked through the land, and that was a strong indictment against any measure. Therefore they would be only doing their duty as peaceful citizens of this Empire in asking for a Special Commission to consider the re-casting of that Act. Under clause 4 of the Act trade unions were relieved in a large measure from responsibility for their acts, and when they found trade unions in a more favourable position as regarded the common law than other sections of the community it made one fear for the future of the community. He submitted that the railway strike had been rendered largely possible by the readiness of the unions to disregard their own rules. The fact that trade unions occupied a favoured position as regarded the law of the land was in itself a bait to attract many men to join the unions. That coercion had been effective lately, but when once the unions were recognised up and down the land was it not to be expected that peaceful persuasion would go on to coerce the free labourer to come into the union? He wanted to see equal justice to all. He moved "That in view of the intimidation and violence which had been openly carried on during the recent railway and other strikes, and of the serious interference, not only with the supply of food and other necessaries of life to the people, but also with the home and foreign trade of the kingdom, this meeting of representatives of Chambers of Commerce of the United Kingdom hereby calls upon the Government to appoint at once a Special Commission to inquire into the working of the Trades Disputes Act of 1906, which in the opinion of this meeting has, by authorising peaceful picketing and relieving trade unions from responsibility for their acts, made possible much intimidation, violence and interference; and that copies of this resolution be forwarded to the Prime Minister, the Chancellor of the Exchequer, the Home Secretary, the President of the Board of Trade and the Leader of the Opposition."

After discussion the resolution was carried unanimously.

National Insurance Bill.—On the motion of Mr. Hobson (Sheffield), a resolution was unanimously passed urging the postponement of the National Insurance Bill, and pledging the meeting in that case to appoint a special committee of the association to put forward the detailed views of the commercial community, with the object of a workable measure being passed which will be acceptable to both employers and employed.

Workmen's Compensation.—A resolution calling upon the Government to appoint a Committee to inquire into the working of the Workmen's Compensation Acts was also passed.

Cleethorpes.—The Council have been authorised to borrow £4,000 for electricity supply works.

Dock Lighting.—Among the improvements that are being made at Methil Dock, N.B., is the installation of plant for the generation of electrical energy for power and lighting.

Dungiveen (Ireland).—Electricity supply for public and private lighting was available for the first time on Aug. 18.

Electric current is supplied at 220 volts from a gas-driven station of Mr. Alex. Semple, J.P. Overhead cables are employed and metal filament lamps of 50 c.p. each are used for street lighting. The contractor was Jas. E. M'Laughlin, and Mr. May was consulting engineer.

Exhibitions.—The North of England Exhibition, which it is proposed to hold in the Queen's Rink, West Hartlepool, from Nov. 13 to Dec. 9, inclusive, is being organised for the display of engineering appliances, motors, &c., together with colliery mining, electrical and horticultural machinery. The general manager of the exhibition is Mr. Geo. Scott, 7, Victoria-road, West Hartlepool.

On Monday afternoon the Mayoress of Ilkeston (Mrs. Shaw) opened an electrical exhibition in the Town Hall of electric cooking, lighting, heating and power apparatus, &c.

A number of prominent firms, including Siemen Bros. & Co., the Osram Electric Lamp Works, the Jandus Arc Lamp & Electric Co., Ferranti Limited, the Union Electric Co., the British Westinghouse Co., &c., had exhibits on show, and demonstrations of cooking, heating, lighting, &c., are given daily from 3 to 10 p.m. The exhibition, which remains open until to-morrow (Saturday) evening, has been organised by the borough electrical engineer and tramways manager (Mr. H. P. Stokes), and has aroused considerable local interest.

Glasgow.—Acting on a report of the general manager of the tramways (Mr. J. Dalrymple) the Tramways sub-committee have unanimously agreed to apply for powers to construct lines to Milngavie, Coatbridge and Clarkston from the present tramway termini.

Huddersfield.—The new tramway route from Holly Bond-road, Edgerton, to the borough boundary at Birchencliffe was opened for traffic on Tuesday.

Negotiations have taken place for the extension of the Huddersfield municipal tramways into Elland. Huddersfield Corporation are willing to extend the lines to the top of the Ainleys, and to apply for the necessary Parliamentary authority.

Liverpool.—As announced in our last issue, the threatened general strike in consequence of the dispute between the Tramways Committee and a section of the tramway employés, was averted at the last moment by the Committee undertaking to reinstate the men out on strike "as and when required."

During the week these men have been reinstated in batches and the last batch was re-started on Monday. The dock and other strikers have also resumed work and things have now assumed almost their normal condition at Liverpool.

On Monday morning the general manager of the tramways (Mr. C. W. Mallins) had a gratifying experience when the last batch (60) of the

Digitized by Google

uniformed men resumed work. The men assembled in the large hall at the Hatton-garden buildings, where an interview was held with the general manager. In the course of a brief address, Mr. MALLINS said that everything possible would be done for the men, so that they might be able to resume work as speedily as possible. He believed that in a day or two the last vestige of the strike would have disappeared, and that all the men would be reinstated and comfortable once more.

Driver WILLIAMS *proposed* a vote of thanks to Mr. Mallins for the highly sympathetic way in which he had received the men, adding that they were exceedingly pleased with the concessions which Mr. Mallins had made while the strike lasted. It was added that the men had been misled, and the general manager could rest assured that they would never take part in another strike, if one, unfortunately, should occur.

Last week a deputation, representing those who had been voluntarily assisting in running the electric power station during the strike, met the chairmen of the Committee (Sir Charles Petrie) at the City Electrical Engineer's Office, Hatton-garden. The deputation handed to Sir Charles a list containing the names of nearly 500 voluntary workers, and suggested that the list might form the basis of a permanent association of citizens willing to help the administration in any similar emergency.

Sir CHARLES PETRIE, in heartily welcoming the proposal, said that he would be glad to give facilities for for any who might desire it to become more intimately acquainted with the practical details of the working of the stations. He expressed on behalf of the Tramways Committee and himself (as chairman) the highest appreciation of the spirit shown by the voluntary helpers, without whose assistance it would have been impossible to continue the electric supply service. He considered that the city generally owed a debt of gratitude to the gentlemen who at great sacrifice of personal comfort and convenience had stepped forward to prevent the city being plunged in sudden darkness, the effect of which in the present disturbed state of affairs might have had most disastrous consequences. He trusted that the deputation would be good enough to convey his appreciation for their patriotic assistance to every member of the band of voluntary assistants.

At a meeting of the men at the power station who went out on strike on 24th inst., Mr. Ross (local secretary of the men's union) spoke.

Mr. Ross said their relations with the electrical engineer (Mr. A. Clough) and the consulting engineer (Mr. A. Bromley-Holmes) were as nice that day as ever they were. Those gentlemen were naturally sore at the men being drawn out without giving the Committee longer notice than they did. He had assured those officials that there had not been the slightest malicious intent on the part of the men, nor any intention of placing the city in darkness, which would have been a very serious thing. The only reason they came out when they did was one of tactics pure and simple. He had given a pledge to the officials that if ever a similar trouble arose again they would give the Committee reasonable notice before they left work. Complaint was made that three men had gone back to work during the night, which was contrary to the instructions of the strike leaders. He said a pledge had been given to the officials at Lister-drive station that as soon as the reinstatement of the uniformed men had taken place the power men would all go back.

L.C.C. Tramway Employés.—On Friday there was a special meeting of the Highways Committee of London County Council to consider certain demands of the men for higher wages, &c.

At the conclusion of the meeting, Sir Laurence Gomme, clerk of the Council, made an official statement to the effect that the Highways Committee had unanimously agreed to arrange for a meeting of the Conciliation Board during the first week of the meetings of the committees of the Council in October next. The Highways Committee also requested the chairman (Mr. F. Hall, M.P.) and the vice-chairman (Mr. Squires) to meet a deputation, which was in attendance, from the Amalgamated Association of Tramway and Vehicle Workers, to ascertain and deal with their grievances in matters not referable to the Conciliation Board. The chairman and vice-chairman would have power to deal with all matters which did not involve further expenditure by the Council.

Mr. Hall and Mr. Squires saw the deputation after the meeting, and the men subsequently met Mr. Fell, the chief tramway officer, in order to discuss matters.

Maldens and Coombe.—As Wimbledon Corporation have now obtained sanction to extend their electricity supply mains to this area the work will be taken in hand at once and a supply of current will be available before the winter sets in.

Metal Lamp Patents.—In regard to the announcement on this subject made in our issue of the 18th ult. (p. 757), the managers of the "Z" Electric Lamp Mfg. Co. (Messrs. Kilburn, Brown & Co.) write as follows:—

Our attention has been called to a statement under the above heading appearing in your journal of the 18th Aug. addressed to you by the Osram Lamp Works (Ltd.), to which is appended a notice of an order made in reference to an action brought by that company against the British Tungsten Lamp Co. (Ltd.). As one of the various manufacturers referred to in that letter against whom litigation has been commenced, we desire to call your attention to the fact that the order referred to was made with the consent of the defendants, who took no steps to defend the action. The business of the British Tungsten Lamp Co. was in the hands of a receiver for the debenture holders, who did not feel justified in contesting the proceedings. The point is material, as your correspondent's letter might convey the impression that the order was the outcome of an investigation by the court. We may add that the proceedings instituted against us are being defended, and we are content to await the decision of the court.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

Moseley.—The City of Birmingham electric supply department have decided to lay electricity supply mains in this district.

Pittington.—The local Co-operative Society recently installed at their premises electric lighting and power plant, including a 16 B.H.P. Tangye gas engine and dynamo, and a battery of 27 storage cells.

Rural Telephones.—The Postmaster-General (Mr. H. Samuel) referred at a meeting of the Cleveland Agricultural Society last week to the transfer of the telephone undertaking and said that the Post Office were making an effort to serve the agricultural interests of the country in relation to telephones.

Wages in the Metal, Engineering and Shipbuilding Trades.—The Board of Trade have issued a report for 1906 on the earnings of workpeople engaged in the metal, engineering and shipbuilding.

The return puts the workpeople employed in those industries in 1906, at 1,500,000. The return relates to 744,557 workpeople, of whom 67·5 per cent. were time workers and 32·5 per cent. piece workers. Their average earnings for a full week were 27s. 4d. The average for engineering and boilermaking was 35s. 11d. and 39s. 1d. in iron and steel manufacture, 34s. 4d. in pig iron manufacture, 30s. 9d. in railway carriage and waggon building, and 31s. 4d. in manufacture of light iron castings, &c.

The following summary shows the average annual earnings (approximately) per head:—

	£ s. d.
Pig iron	79 0
Iron and steel	82 0
Tinplate	74 10
Engineering and boilermaking	69 0
Ship, &c., building and repairing	70 10
Railway carriage and waggon	66 10
Light iron castings	59 0
Average for all metal trades	68 10

The average number of hours constituting a full week were:—Pig iron, 55·2; iron and steel, 54·4; tinplate, 47·8; engineering and boilermaking, 53·1; ship, &c., building and repairing, 52·9; railway carriage and waggon 53·6; and light iron castings, 53·8. For all the trades included, the hours averaged 53·2 per week.

In engineering and boilermaking the earnings are classified into 14 districts. For the whole country the average earnings for the census week (end September, 1906) of adult males who worked full time were 32s. 5d., and for all men, including those who worked more or less than full time, 31s. 11d. The figures include labourers. The average earnings of men working full time in engineering and boiler making was:—

	s.	d.		s.	d.
London	38	0	Southern & South-Western Counties	31	8
Tyne, Wear & Tees	35	8	Remainder of Lancashire & Cheshire	31	4
Mersey & Barrow	35	5	North & West Midland Counties	31	4
Clyde	33	6	Remainder of Yorkshire	30	4
Sheffield	33	0	Remainder of Scotland	30	2
Manchester	33	0	Leeds	29	10
11 Lancashire Towns	31	8	Remainder of United Kingdom	29	3

In the electrical engineering industry, telegraph apparatus manufacture &c., the average was 34s. 7d.; wire drawing and working, 35s. 7d.; brass and allied metal wares, 31s. 9d.

Wireless Telegraph Notes.—In the "Australian Mining Standard" for July 27 there appeared a lengthy note on the effect of the recent judgment of Mr. Justice Parker in the action of the Marconi Company against the British Radiotelegraph Co. The purpose of the note is to set out certain differences of opinion which have arisen over Mr. Justice Parker's judgment. The opinions expressed on the subject editorially in THE ELECTRICIAN come under review.

The "Manchester Guardian's" London correspondent understands that a committee has been formed to consider and recommend what steps should be taken to establish a chain of British State-owned wireless stations within the Empire.

The committee (the correspondent continues) consists of representatives of the home Government and of the Governments of Australia and New Zealand. A preliminary meeting has already been held. A beginning is to be made with a chain of six stations in England, Cyprus, Aden, Bombay, Straits Settlements, and Australia. From Western Australia the messages will be carried over the land-lines to Sydney, and thence to New Zealand. The cost of the stations in England and Cyprus will be borne by the home Government, those at Aden and Bombay by the Government of India, those in Australia and New Zealand by the Governments, while the cost of the station at Singapore will be shared by all the Governments concerned except Australia. The selection of sites for the several wireless stations on the route will be taken in hand at once.

Digitized by Google

COLONIAL AND FOREIGN NOTES.

Argentina.—The tramways in the City of Corrientes, owned by Senor Dodero, are to be converted to electric traction.

A telephone network to connect the various departments in Corrientes province with the capital is to be erected.

An electricity supply company has been formed at Carmen de Areco with a capital of $100,000. Mr. R. Pearson Hale is chairman.

An electric lighting and tramway company with £250,000 capital, and with Mr. V. Jauregui as chairman has been formed in Lujan (Buenos Ayres Province).

The plant at the power house of the Cia Alemana Transatlantica de Electricidad at Avellaneda, Buenos Ayres, is to be increased to 50,000 H.P., several new sub-stations are to be built and others will be enlarged.

Australasia.—The Premier of Western Australia (the Hon. F. Wilson) has announced that it is the intention of the Government to proceed with the nationalisation of the Perth tramways, provided that the company is willing to sell its undertaking at a reasonable figure.

Negotiations for the supply of electrical energy by the Bellambi Coal Co. to the Bulli (N.S.W.) Shire Council for public lighting have been renewed.

Sydney Council have entered into agreements to supply electricity to the local authorities of Glebe, Woollahra, St. Peters, Darlington, Randwick, Erskineville, Botany and Alexandria.

Sydney Council recently decided to appoint an assistant installation inspector at £187 per annum.

The directors of the Tallangatta (Victoria) butter factory recently visited the electricity works of other towns with a view to making recommendations as to establishing similar works at Tallangatta.

In evidence before the (Melbourne) Metropolitan Traffic Commission, Mr. T. B. Malomby, superintendent of the Victorian passenger train service, said he was in favour of electrical power, and was sure it would give better results than steam. Mr. J. M. Jolly, manager of the Australian Metal Co.'s electrical department, said he was in favour of the overhead system and the big type of car for the Melbourne tramways. If the electrification were to extend more than 10 miles from the city, modern practice recommended the use of alternating current, but if restricted to the suburbs direct current would have advantages.

The special committee appointed to deal with the acquisition by Hobart (Tasmania) Council of the undertaking of the Hobart Tramway Co. have expressed the view that the limit to which the Council should go in purchasing the company's rights and powers is £150,000, which would mean an annual payment of £7,500 for interest and sinking fund. The company ask for a much larger price.

Launceston (Tasmania) Council have been considering the question of putting in auxiliary generating plant, and it is regarded as certain that steam-driven plant of about 1,000 H.P. will be decided upon.

Mr. Vaughan, the South Australian Treasurer, recently stated in the Legislative Assembly that the Government had advanced £1,323,483 to the Municipal Tramway Trust for the purchase of the old lines and the construction of the new system.

The Victorian Electrical Installation Board is to consist of Messrs. W. Cumming, E. Bridger and H. Rowe, representing the employers, and C. S. Willers, W. R. Stewart and Wm. R. Thomson, representing the employés.

In future the Australian Postmaster-General's department will present an annual report to Parliament, as do the various State departments.

A report recently presented to the Victorian Parliament shows that in 1910 ten applications for Orders in Council were made under the Electric Light and Power Act, and the following eight were granted: Melbourne Electric Supply Co. (for Brighton and Camberwell), South Gippsland Butter Factory Co. (for Yarram), Defence Department (for portions of Braybrook and Footscray), Tatura Butter Factory Co. (for Tatura), Upper Yarra Shire Council (for Warburton), Charlton Electric Light & Power Co. (for portions of town and shire of Charlton), Footscray Council (for Footscray). The Footscray and cordite factory supplies will be obtained from Melbourne City Council, and that for Warburton from the Signs Publishing Co. The Prahran and Malvern Tramways Trust has been empowered to use and supply electricity. Preliminary enquiries were made with the view of obtaining orders for Birchip, Euroa, Numurkah, Daylesford, Rainbow, Dandenong, Yea, Ararat and Woodend.

Austria-Hungary.—Innsbruck municipality are acquiring the Achensee, with certain buildings, at a cost of about £167,000, with the view of establishing hydro-electric works.

A scheme for developing 7,500 H.P. of electrical energy for steel works to be erected between Kitzbühel and Oberndorf, by means of water-power from the Aschaver Ache, is to be carried out by Salzburg electrical engineers with the assistance of the Länderbank.

The communal authorities of Kgl. Weinberge are about to construct electric tramways, and Vienna Town Council have also decided to lay down tramways.

Brazil.—Imports at the port of Santos in 1910 included electrical appliances valued at £216,518 (compared with £77,087 in 1908 and £102,606 in 1909), industrial machines £188,478 (against £186,330 and £173,127), "water engines," £41,489 (against £46,690 and £29,142) and sundry machines and implements, other than agricultural, £390,373 (against £286,919 and £242,245).

A by-law has recently been passed by the Municipal Council of Salvador, the capital of the State of Bahia, instructing their superintending engineer to cancel the concession granted to the Companhia d'Eclairage de Bahia, subject to compensation, and to invite tenders for the supply of current for public and private lighting and for power purposes in the city for a term of 60 years.

Canada.—Though little more than a year old, the town of New Waterford, in a newly discovered coalfield in Cape Breton County, Nova Scotia, has a population of 5,000, and is lighted electrically.

India.—"Indian Industries and Power" states that a licence has been granted by the Municipal Commissioners of Chittagong to the agents of the A.E.G. for the supply of electricity to the town.

The Municipality have decided to light the main streets electrically. The preliminary scheme is being drafted by Mr. H. R. Speyer, who will be responsible for the engineering portion of the undertaking, and Messrs. Turner, Morrison & Co. are representing the commercial interests of the A.E.G. at Chittagong.

Japan.—The British Acting Commercial Attaché for Japan states that the capital embarked in new engineering and transport enterprises in the years 1907, 1908, 1909 and 1910 was as follows:—

	1907.	1908.	1909.	1910.
Electrical	£5,778,000	£1,549,000	£840,000	£9,349,000
Mining	5,354,000	495,000	876,000	2,266,000
Railway	6,663,000	1,137,000	1,409,000	9,285,000
Manufacturing	20,038,000	3,230,000	3,167,000	14,215,000
Transport	3,935,000	1,108,000	306,000	860,000

A factory for making incandescent electric lamps has been established and experiments in that direction are being carried out in Osaka.

During the year steady progress was made in the direction of extending the use of hydro-electric power. In October the Kinugawa Hydro-Electric Power Co. was formed with a capital of 13,500,000 yen (£1,378,000) to supply Tokio with electricity generated by the waters of the Kinu River.

In April a Government commission was appointed to examine and make a record of the water-power resources of the country. The hydro-electric works, for which charters have been granted, will have an ultimate capacity of 592,000 kw. A number of these power stations are in course of erection or in contemplation.

Russia.—Amongst projected and authorised railways in Russia is the Oranienbaum electric railway, the two sections of which will total 41 miles.

United States.—Exports of electrical goods from the U.S.A. for the 12 months ended June 30 last include heavy machinery to the value of $8,024,028, against $6,048,263 in the previous year, and instruments and apparatus $10,702,827 ($8,694,132). More than a fourth of these exports ($4,912,189) were sent to Canada (against $3,557,954), while the value of those sent to Japan was $2,215,173, Mexico $2,468,888, and Brazil $2,446,041.

Uruguay.—The Oficina Técnica Hércules has been authorised to make surveys for an electric railway to the port of La Paloma y Rocha.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Bury St. Edmunds.—In a report on the past year's working of the electricity undertaking, the borough electrical engineer (Mr. Sydney E. Day) states that the year's results could not be considered other than satisfactory, and the all-round expansion of the business was most marked.

Mr. Day states that the number of new consumers connected during the year had been well maintained, and there was an increase of over 20,600 in the units sold, representing about £450. There was also an increase in the works cost, for which the coal bill was mainly responsible, and the inefficiency of the condensing plant and its inability to deal satisfactorily with the heavy winter loads was in no small measure responsible for the increased coal consumption. The removal of the condensing plant and the thorough overhauling of the plant, which was now in hand, would practically overcome the difficulty and a marked economy in fuel consumption should result. Advantage had been taken of the arc lamp hire scheme introduced in the early part of the year, there being about 14 lamps on hire at present. Much satisfaction was being obtained from these lamps. The popularity of the prepayment meter was growing.

Cardiff.—The accounts of the electricity supply department for the year ended March show capital expenditure £272,250 (increase £3,820.)

Revenue was £45,455 and working and general expenses were £27,638, leaving gross profit £17,817, and net surplus of £909 (compared with £94) after meeting capital charges, &c. Units generated were 5,952,502, supplied to public lamps 1,214,650, minimum 3,401, private consumers by meter 3,630,824. There are 618 arcs and 178 incandescents for public lighting. The total maximum demand was 2,694 kw. The report of the city electrical engineer, Mr. Arthur Ellis, states that the department has suffered as a result of the introduction of metal filament lamps, but he thinks it has now begun to reap the benefits accruing from the metal filament lamp which has reduced the cost of electric light so as to bring it within the reach of a larger body of people. There is ample evidence

Digitized by Google

that builders prefer electric light when erecting new property, as it enables them to sell the property more readily. The number of consumers increased by 247 making a total of 2,106. Of the 4,848,875 units sold (compared with 4,561,682 in previous year), 1,416,182 were for power purposes. There are 546 motors connected = 3,688 H.P.

Wellington (N. Z.) -The accounts of the electric lighting department for the year ended March 31 last show capital expenditure £224,304 (increase £6,344) and revenue contribution to capital outlay was £23,910 (against £19,961 in previous year.)

Revenue was £45,587 (against £44,814), working expenses were £23,609 (against £25,933) and the net surplus, after meeting capital charges and placing £6,986 (£6,361) to depreciation, was £4,345 (£2,228). Units generated were 3,251,549 (against 2,770,379), and units sold were 2,056,617 (2,018,526). There are 5,368 (4,501) consumers, the lamps connected are equivalent to 193,692 (170,627) 8 c.p. lamps, and the total horse-power of motors connected is 1,252 (1,187).

The capital expenditure on the tramways department is £619,865 (including £39,530 for power supply and public lighting), compared with £595,781 at March, 1910. The total revenue (tramway and power supply) was £142,788 (£139,460) working expenses were £95,965 (£92,946), and after meeting capital charges and placing £14,408 (£14,202) to depreciation, the net surplus is £6,226 (£6,123). The passengers carried (on the city lines) were 22,604,235 (21,932,507) and car-miles run (on all lines) were 2,250,291 (2,203,666).

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1911 Edition of the Big Blue Book is READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 24th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1911 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

Tenders are invited up to Oct. 18 for the supply of 20 coin-in-the-slot attachments to the Postmaster-General's Department in WESTERN AUSTRALIA. Specifications, forms of tender, &c., may be obtained at the Commonwealth Office, 72, Victoria-street, London, S.W. See advertisement.

The Postmaster-General's Department in SOUTH AUSTRALIA require tenders up to Oct. 25 for supply of cable and paper sleeves. Tender forms and specifications may be obtained from the Commonwealth Office, 72, Victoria-street, London, S.W. See also an advertisement.

The Postmaster-General's Department in TASMANIA want tenders by Oct. 2 for supply of 10,000 porcelain insulators. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See also an advertisement.

The WESTMINSTER ELECTRIC SUPPLY CORPORATION invite tenders for supply, delivery and erection at their Davies-street station of battery boosters and switchboards. Copies of specification, with drawing and general conditions can be obtained from the Secretary of the Corporation, Eccleston-place, Belgravia, S.W., to whom tenders should be sent by 10 a.m. of Sept. 12. Specification can be seen at (but not obtained from) the offices of the consulting engineers (Messrs. Kennedy and Jenkin), 17, Victoria-street, Westminster, S.W.

Tenders will be received until noon Monday, Sept. 18, for the supply of Swedish, Norwegian, Finland or Russian red fir telegraph poles, for the GENERAL POST OFFICE. Forms of tender from the Controller of Stores, Mr. G. Morgan, Stores Department, G.P.O., 17 and 19, Bedford-street, London, W.C.

ECCLES Electricity Supply Committee require tenders by noon, Sept. 12, for supply and erection of h.t. single phase a.c. switchboard. Specification, &c., from the Borough Electrical Engineer.

HASLINGDEN Council require tenders by noon Sept. 9 for the electric lighting of various buildings owned by the Corporation. Specifications, &c., from the Electrical Engineer, John-street, Haslingden.

PONTYPRIDD Council want tenders by noon Sept. 12 for supply and erection of water tube boiler and Foster superheater. Specification, &c., from Mr. J. E. Teasdel, Electricity Works, Treforest.

The Electricity Supply Committee of DUBLIN Corporation invite tenders for supply of 750 a.c. meters (single phase) and 200 a.c. (three phase) meters. Tenders to the Chairman of the Committee, 3, Cork-hill, Dublin, by noon Thursday, Sept. 7.

Tenders are invited up to Sept. 26 for supply of telephone material and 30 miles of telephone cable, and up to Oct. 3 for the supply of 42 miles of telephone cable to the Postmaster-General's department in VICTORIA. Tender forms and specifications at the Commonwealth Office, 72, Victoria-street, London, S.W.

The Metropolitan Water and Sewerage Board, Albert-street, BRISBANE, Queensland, want tenders by noon Jan. 30 next for supply and erection of one, two or three complete units, each consisting of power generating plant and pump or pumps to lift not less than 6,000,000 gallons per day. Particulars from the Secretary, and forms from the Agent-General for Queensland.

Tenders are invited by the Municipal Council of PELOTAS (Brazil) for a 40 years' concession for the supply of electricity for power and lighting and the establishment and working of electric tramways. Tenders to Senhor Luiz M. da S. Pennafiel, Intendencia Municipal, Pelotas, up to 1 p.m. Nov. 14. A deposit (about £300) is required with each tender, to be increased by the successful tenderer to 25,000 milreis (about £1,670). Further particulars (in Portuguese) can be seen by British contractors at 73, Basinghall-street, London, E.C.

The Municipal Council of BUDAPEST, Hungary, require tenders for the manufacture and supply of plant for a steam-driven electrical generating station, including two groups of three-phase turbo-generators (5,000 kw. each), 10,000 volts 50 cycles, boiler equipment for mechanical output of 5,000 kw. with reserve, pipeline, central switching and accessory equipments, travelling crane for engine room and coal-conveying plant. Specifications, &c., can be obtained at the Presidial Section of the Council, 9: IV., Városház-utca 16, II. 1, Budapest. Tenders by 11 a.m. Sept. 30.

Tenders will be received at the Town Hall, SYZRAN, Russia, on Oct. 14, for the construction of an electric tramway and the supply of electrical energy for lighting.

The Public Works Department, Madrid, will receive tenders on Sept. 20 for the concession for the construction of the RENTERIA electric tramway.

The Municipal Commissioners of PENANG invite tenders for the supply and delivery, f.o.b. British port, of one 500 kw. steam dynamo engine or turbine with ejector condensing plant and switchgear. Specifications from the consulting engineers, Messrs. Preece, Cardew & Snell, 8, Queen Anne's-gate, Westminster, S.W., to whom tenders (in duplicate) by noon of Tuesday, Sept. 5.

Tenders will be received at the Prefecture, CANEA (Crete), until Aug. 30 for supply of 5,500 kilogs (about 5½ tons) of telegraph wire.

The Danish State Railways Administration, COPENHAGEN, require tenders by 1 p.m. Sept. 4 for supply of 936 accumulators for train lighting. Specification (in Danish) may be seen at 73, Basinghall-street, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

Among recent contracts secured by the Electrical Power Storage Co., 4, Great Winchester-street, London, E.C., are the following:—

Devonport Corporation, renewing 261 cells of lighting battery, having a capacity of 670 ampere-hours, also renewing part of traction battery, each cell having a capacity of 2,000 ampere-hours, at £1,[illegible] and maintenance of same for 10 years.

Birkenhead Corporation, supplying new battery of 260 cells, 1,350 ampere-hours capacity, at £1,771, and maintenance for 10 years.

Bispham Council have accepted the following contracts in connection with their electricity undertaking: National Gas Engine Co., engines and dynamos; Kelvin & James White, switchboard, balancers and boosters; Premier Accumulator Co., storage battery; British Insulated & Helsby Cables, mains; Chadwick Bros., erection of station buildings; Smith Bros., cable trenches, &c.

Sydney (N.S.W.) Council recently accepted the tender of the Australian General Electric Co. for supply of switchgear and transformers at £3,500, and purchased electric cooking apparatus from

Digitized by Google

Wm. Adams & Co. at £25 and single-phase meters for large motors from the A.E.G. at £95.

Auckland (N.Z.) Council have received the following tenders for plant for their generating station :—

Engine-room Plant.—Greenshields & Co., £42,592; General Electric Co., £50,181, £41,768 and £38,419; Turnbull & Jones, £37,841 and £40,310; George Fraser, £37,946. 10s.; Belliss & Morcom, £40,570, £41,360, £41,990 and £40,070; A. & T. Burt, £37,360 and £23,105; National Electric Co., £38,596, £38,126, £31,066 and £37,881; Brush Co., £32,410; Grey Thorpe, £39,028; Wm. Adams, £34,795.

Boiler-house Equipment.—J. Chambers, £21,844; J. Howden & Co., £15,800. The tenders were referred to the Electricity Committee and the City Electrical Engineer.

The Government Electric Supply Department at Montevideo has accepted the tender of Cooper & Sons, on behalf of Colson, Brookhouse & Pyne, for supply of 200 km. (124 miles) of insulated aerial conductors, manufactured by British Insulated & Helsby Cables. Seventeen tenders were received, the accepted tender being the lowest.

Commonwealth Contracts.—The Postmaster-General's department in Victoria have accepted the tenders of British Insulated & Helsby Cables for telephone cables (£10,990) and 3,500 copper binders (£3. 5s. per 1,000); Western Electric Co. for telephone cables (£19,879. 14s.); R. Johnson, Clapham & Morris for 3,500 tapes (£1. 16s. 6d. per 1,000); T. Zwicker & Co. for 7,000 insulators (5d. each); and Gibbs, Bright & Co. for 11 tons h.d. copper wire (£68.10s. per ton).

BUSINESS NOTICES.

The telegraphic address of the publishing department of the British Westinghouse Co. will be in future, "Westinghouse Manchester," and not "Unappalled Manchester."

The Standard Cable Mfg. Co. (Ltd.) have opened a contract office at 98a, St. Vincent-street, Glasgow.

A. A. Kerridge and H. Sloman (trading as the Starlight Electric Co.), 38, Alexandra-road, Southend-on-Sea, have dissolved partnership. Debts by Mr. Kerridge, who continues.

Patents Development.—The proprietor of patents No. 13,427/06 and 880/07, for "Improvements in dynamo electric machines," desires to make arrangements for exploiting same in this country. Applications to Messrs. Haseltine, Lake & Co., patent agents and consulting engineers, 7 and 8, Southampton-buildings, Chancery-lane, W.C.

The owners of patents No. 23,501/99, relating to "Improvements in vacuum tube lighting," and No. 12,582/02, relating to "An improved system of electric lighting," also desire to negotiate with electrical engineers with the view of granting licences. Applications of Messrs. Lloyd Wise & Co., patent agents, 46, Lincoln's Inn Fields, W.C.

BANKRUPTCIES, LIQUIDATIONS, &c.

The Havana Telephone Securities Co. (Ltd.) is being wound up voluntarily, and Mr. Geo. Banks, New Broad-street House, London, E.C., is liquidator.

Broadstone (Ltd.) (which formerly owned the Fleetwood electricity works) is being wound up voluntarily. Mr. G. E. Conolly, Bank-chambers, Woolwich, is liquidator. Meeting of creditors Sept. 8 at offices, Whale & Wates', 107, Cannon-street, London, E.C.

A meeting of creditors of the Simplex Acme Patent Fire Alarm Co. will be held 7, Sweeting-street, Liverpool, on Sept. 4.

The liquidator (Mr. S. P. Child, 8, Frederick's-place, Old Jewry, London, E.C.) of the Phosphor Bronze Co. (Ltd.) has been released.

A dividend is to be paid to creditors of W. H. Ridpath (trading as Ridpath & Wells), electrical engineer, 20, Bath-street, Ilkeston. Claims to Mr. E. W. Humphreys, 5, Victoria-buildings, Derby, by Sept. 9.

The examination of Fredk. Vickers, electrical engineer, took place at Manchester on Friday last. It was stated that debtor commenced business in November, 1908, without capital. He did electrical installation work. One creditor gave him credit to the amount of £250. After removing 18 months ago to 286, Oxford-road, Manchester, he lost money on contracts for which his foreman had given estimates which were too low. Unsecured liabilities were £1,—and assets £58. The examination was closed.

COMPANIES STRUCK OFF THE REGISTER.—The following were struck off the register of Joint Stock Companies on Aug. 29:—

Aberdare Electric Lighting Co., Albion Battery Co., Buenos Ayres Electric Light Co., Heswall District Power Co., Private Wire & Telephone Installation Co.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

*NOTE.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

July 10, 1911.

15,933 WALKER & WAYGOOD & Co. Control of electrically-operated lifts, elevators and the like. (Divided application on 20,118/10. Aug. 29.)
15,959 LOWY & MULLER. Production of electro-deposits. (Convention date, 1/6/11, Austria.)*
15,998 B.T.-H. Co. (G.E. Co., U.S.) Means for handling freight and apparatus therefor.
16,007 GRAFTON & PRIOR. Automatic control of dynamo-electric machines in direct-current distributing and consumption systems.*

July 11, 1911.

16,026 VAUGHAN. Sparking-plugs.
16,068 ELECTRIC & ORDNANCE ACCESSORIES Co., ETCHELLS & PRICE. Variable-speed dynamos.
16,074 BROWN. Sending mechanism for party-line signalling. (Convention date, 11/7/10, United States.)*
16,075 WESTERN ELECTRIC Co. (Western Electric Co., U.S.)* Telephone Exchange Systems.
16,081 PRICE. Electric plug connection.
16,088 ARON. Systems for electrically controlling or operating clocks or the like.
16,093 WARWICK MACHINERY Co. (1908). (A.E.G., Germany.) Speed-regulating devices.

July 12, 1911.

16,095 MOORE, GAMBRELL & GAMBRELL. Dynamometers, wattmeters, watthourmeters and the like.
16,096 ELFORD. Contact-breakers for induction coils and other purposes.
16,143 BASTIAN. Envelopes or supports for the resistances in electric-heating apparatus.
16,163 B.T.-H. Co. (G.E. Co., U.S.) Electric lamps.

July 13, 1911.

16,187 ANDERSON & BURNSIDE. Mercury or other vapour electric apparatus.*
16,195 SCHALLER. Electric incandescent lamp. (Convention date, 13/7/10, Germany.)*
16,228 GRAHAM. Fuses for electric circuits.*
16,230 BLOCH. Method of and apparatus for regenerating burnt out carbon and metal filament electric lamps.*
16,234 Creighton. Protective devices of the type known as lightning arresters. (Convention date, 5/7/10, U.S.)*

July 14, 1911.

16,271 HEWITT. Light transforming reflectors. (Convention date, 23/7/10, U.S.)*
16,298 BOWRON. Electric oscillographs.

July 15, 1911.

16,318 WILSON & WARREN. Type of electric lamp holder.
16,343 ELECTROMOTORS (LTD.) & GREENHALGH. Controlling the speed of electro-motors.
16,352 MITCHELL. Telephone call apparatus and the like.
16,355 FRASER. Direct-current transformers and the like.
16,361 BARBOUR. Control of alternating-current electric motors.
16,367 OGILVY-WEBB & REINECKE. Arc lamps.
16,372 SUBMARINE SIGNAL Co. & EVANS. Submarine signalling-apparatus.
16,374 LAKE. (David Leonard Lindquist, U.S.) Traction electromagnets.*

July 17, 1911.

16,426 ELEKTROCHEMISCHE WERKE G.M.B.H. Process for the electrolytic production of ammonium nitrate from hydrated nitric acid. (Convention date, 16/7/10, Germany.)*
16,437, 16,438 MACKENZIE. (Champion Ignition Co., U.S.) Spark plugs.*
16,440 ANSCHUTZ & Co. Electrical Contacts. (Convention date, 26/11/10, Germany.)*
16,456 KAISER. Electrical driving devices for sound reproducing machines.*
16,456 LEGRAND & ARMEL. Electrically-operated apparatus for locking railway carriage and other doors. (Convention date, 27/7/10, France.)*
16,469 STROUDE & JOSEPHS. Electrical measuring instruments.

July 18, 1911.

16,488 WOODHOUSE. Terminal and like boxes for use with conduits or casings for electric conductors.
16,489 WOODHOUSE. Conduits or casings for electric conductors.
16,498 DAVIS. Electrical conducting cables and the like.
16,514 LUNDBERG, LUNDBERG & LUNDBERG. Electrical terminals.*
16,523 DARE. Portable field-telephoning apparatus.
16,528 SIEMENS BROS. & Co. (Siemens & Halske Akt.-Ges., Germany.) Safety devices for locking appliances. (Addition to 20,779/07.)*
16,532 SCOTT. Electric lifts.
16,533 MULLER. Protecting insulated conductors against fire. (Convention date, 3/8/10, Austria.)*
16,542 SMITH & SHUTER. Covering of electric conductors with plastic material and apparatus therefor.*
16,547 DENNY. Electric fuses or cut-outs.
16,553 CHAPMAN & GRIMSLEY. Apparatus for recording telephone calls.
16,554 DEARLOVE & BROWN. Manufacture of electrical condensers and similar apparatus.

July 19, 1911.

16,584 ADAMS. Electrical combined switch and fuses.
16,602 LOFQUIST. Device for heating running water or other liquid by electricity.*
16,604 BENZ & Co. RHEINISCHE GASMOTOREN FABRIK AKT.-GES. Ignition devices for internal combustion engines operated by heavy hydrocarbons. (Convention date, 19/7/10, Germany.)*
16,644 GASNIER. Electro-mechanical change-speed and reversing device. (Convention date, 19/7/10, France.)*

July 20, 1911.

16,667 MARTIN & CAMPBELL. Controlling and operating electric locomotives, electric trains, electric tramcars and other electric traction machinery.
16,678, 16,679 ENGINEERING & ARC LAMPS and DOWDELL. Arc lamps.
16,694 KINLEYSIDE. Insulating supports for electric conductors.
16,707 KAHN. Telephone and other suitable sound receivers.
16,721 MOORE. Transmitting telegraph keys.
16,727 NATIONAL CASH REGISTER Co. (National Cash Register Co., U.S.) Cash registering machines and electrical control means for same.*
16,737 B.T.-H. Co. (A.E.G., Germany.) Compensation of polyphase commutating dynamo-electric machines.
16,738 B.T.-H. Co. (A.E.G., Germany.) Regulating devices for driving motors of spinning machines.

July 21, 1911.

16,796 HUMPHRYS. Means for connecting electric cables to junction, bifurcating, trifurcating terminal boxes and the like.

July 22, 1911.

16,828 LONGFORD & CLARK. Terminals for ignition plugs.
16,841 RAILING & KRAUSE. Regulators for dynamo-electric machines.
16,859 BAYER & HUBBARD. Electrical secondary or storage batteries.*
16,867 MCBERTY. Automatic telephone exchange selector. (Convention date, 23/7/10, U.S.)*
16,868 WESTERN ELECTRIC Co. (Western Electric Co., U.S.)* Wiring contacts of telephone switches.
16,869 MCBERTY. Semi-automatic telephone systems. (Convention date, 23/7/10, U.S.)*
16,870 WEST & Co. & MOGGRIDGE. Drum-type controllers for the shunt control of electric motors.*
16,871 WEST & Co. & MOGGRIDGE. Liquid electric controllers.*

SPECIFICATIONS PUBLISHED.

1910 SPECIFICATIONS.

9,191 BOOKER, OGILVY-WEBB & REINECKE. Arc lamps. Cognate application, 24,041/10.)
9,580 ARNO. Alternating-current power measurement and instruments for the same.
13,716 CRAWFORD & SCOTT. Tools or machines operated by a reciprocating element and means for driving them electrically.
14,042 JOHNSON & LOXLEY & Co. Electrical ceiling roses, junction boxes, fuses and the like.
14,126 HOLDEN. Electric clocks. (Patent of addition not granted.)
16,258 KALLMANN. Electric safety fuses.
16,552 BOLTINKOFF. Incandescent vapour lamps.
16,653 MAVOR & MAVOR & COULSON. Power installations.
16,763 KLEIN. Alternating current and alternating and direct current machines.
16,904 LICHTENFELD. Switch devices for electric circuits.
17,010 ROSENBERG & PECK. Braking induction motors.
17,107 ADAMS MFG. Co. (Cutler Hammer Mfg. Co.) Control systems for electric motors.
17,172 BONHOMME. Wireless signalling apparatus. (19/7/09.)
17,222 SUMPTER. Controlling a reversing variable-speed motor for driving reciprocating tools, planing and rifling machines, cranes and the like.
17,236 WATKINS. Grinding the contact surfaces of carbon brushes for dynamos, or other purposes.
17,247 JAMES. Electrically driving machines at variable speeds.
17,469 EISNER. Manufacture of filaments for incandescing electric lamps.
17,523 JUDD & HARDIE. Telegraph relays.
17,684 VENNER. Resistance for electric heating apparatus.
18,295 ANDERSON. Manufacturing spark plugs.
18,794 SMITH & MUIRHEAD & Co. Ignition apparatus.
20,900 TUCKER. Electrical switches. (Cognate application, 22,163/10.)
21,206 HARDEN & ELECTRIC FURNACES & SMELTERS. Production of metals from their ores by reduction.
21,235 ROGLER. Motor, more especially designed for use in driving blowers, rolling mills, and electric generators for smelting works.
21,848 CUNNINGTON. Electrical heating radiators.
22,198 PRESSER & GES. FUR ELEKTROTECHNISCHE INDUSTRIE. Automatic regulators for electric circuits.
22,239 WHITE. Intercommunication telephone systems
24,347 PEROTTI. Process and device for transmitting and registering verbal communications by means of the telephone.
24,489 SAMAIA. Apparatus for actuating conduit covers and collector ploughs of electric conduit tramways. (Addition to 8,852/10.)
27,240 BACCI. Incandescent electric lamp.
28,588 WESTINGHOUSE BRAKE Co. (Taylor.) Electric relay apparatus.
28,783 BARBER. Wooden propellers for aeroplanes and the like with an electrically-deposited metal coating.
29,489 ANDERSON. Sparking plugs.
29,802 MURPHY. Producing high-tension electric discharges and electric oscillations.
30,297 COMPAGNIE POUR LA FABRICATION DES COMPTEURS ET MATERIEL D'USINES A GAZ. Electricity motor meters of the mercury type. (2/5/10.)

1911 SPECIFICATIONS.

177 B.T.-H. Co. (G.E. Co.) Systems of electric motor control.
559 COMPAGNIE POUR LA FABRICATION DES COMPTEURS ET MATERIEL D'USINES A GAZ. Electricity motor meters of the mercury type. (Addition to 30,297/10.)
1,100 STROUDE & JOSEPHS. Thermo-electric temperature measuring apparatus.
1,251 WILSON. Incandescent lamp.
2,226 GAUTSCH. Method and apparatus for extinguishing fires in electric cables and electric circuits especially, in telegraph, telephone and similar installations.
2,501 GRAHAM. Water-tight telephonic apparatus.
3,086 CARDWELL. Transmitting electric impulses.
3,422 CAMPBELL & SHAW. Line circuits for the transmission of electrical signals. (12/2/10.)
3,423 SHAW. Line circuits for the transmission of electrical signals. (12/2/10.)
5,267 WESTON. Electrical measuring instruments. (Divided application on 17,091, 18/7/10.)
5,596 SIEMENS BROS & Co. (Siemens & Halske Akt.-Ges.) Railway signalling apparatus. (Addition to 19,558/07.)

COMPANIES' MEETINGS AND REPORTS.

BLACKPOOL & FLEETWOOD TRAMROAD CO.—At the meeting last week the chairman (Mr. Geo. Richardson) said there was an increase of £594 in the profits for the past half-year and the expenditure was less by £25. They had taken from the reserve fund £3,020 for renewals, repairs, &c., but had added £1,750 to that account. They received 6½ per cent. as dividend for the year. The directors were anxious to make the dividend equal but could not legally do so under present conditions. They were to get permission to make up the accounts yearly and for the declaration of an interim dividend. The receipts for the current half-year showed an increase of £750.

KALGOORLIE ELECTRIC TRAMWAYS (LTD.)—At the meeting on Tuesday the chairman (Mr. A. H. P. Stoneham) said that the result of the past year's working was not so good as the previous year's, as the mining industry was not now in a flourishing state. They took their power from the Kalgoorlie Power Co., and that company from time to time had made propositions to them to work the tramways for them under an agreement at so much per mile. There was also a possibility that the State Government would nationalise the Perth tramways The tendency all through Australia was to nationalise all means of locomotion. Whether the State would acquire the Kalgoorlie tramways he could not say.

PERTH ELECTRIC TRAMWAYS (LTD.)—At the meeting on Tuesday the chairman (Mr. A. H. P. Stoneham) said that for eight months of the current year the returns were £10,300 ahead of those of last year, but last year the returns were affected by the strike of motormen and conductors. They had been occupied during the last three months in negotiations for the disposal of the tramways. The people of Perth had come to the conclusion that they ought to own the tramways. When the concession was granted it was granted for 17 miles and the company was now operating over 30 miles of track. The company said they did not want to sell, but if there was to be dissatisfaction among the public, then, rather than have any trouble, they would recommend the shareholders to sell, if a fair price was given. The State were also making inquiries as to the purchase of the lines. The company had an offer of £50,000 new capital on fair terms in case they decided to go on as at present.

NEW COMPANIES, RECEIVERSHIPS, &c.

NEW COMPANIES.

CURTIS & CO. (LTD.) (117,400.)—Reg. Aug. 25, capital £2,000 in £1 shares (1,000 preference), to take over the business of an electrical engineer and medical electrician, &c., carried on by W. Curtis. Private company. First directors: W. Curtis and Elma Curtis. Reg. office: 101, Leadenhall-street, London, E.C.

DARNELL ACOUSTIC CO. (LTD.) (117,382.)—Reg. Aug. 24, capital £100 in £1 shares, to carry on the business of manufacturers of and dealers in electrical and other instruments for deafness, medical or surgical appliances, &c. Private company. Mrs. G. Hincks is permanent governing director. Reg. office: 383, Mansion House, Chambers, London, E.C.

WEAVERHAM ELECTRICITY SUPPLY CO. (LTD.) (117,358.)—Reg. Aug. 22, capital £5.000 in £5 shares, to carry on the business of electrical engineers, electricians, manufacturers of and dealers in electrical apparatus, suppliers of electricity, &c., in Weaverham and district. First directors: J. W. Smith, W. H. Burgess, G. H. Dean, R. Howarth and R. N. Gandy.

RECEIVERSHIP.

THOMAS BRITTAN (LTD.)—Notice of appointment of J. W. Vincent, 6, Holborn Viaduct, E.C., as receiver, by order of Court dated Aug. 16, has been filed.

ARGENTINE TRAMWAYS.—The "Review of the River Plate" states that the shareholders of the Cia de Electricidad de la Provincia de Buenos Ayres recently approved a proposal by an English syndicate to acquire all the $100 shares of the company for $100 cash and one $100 share in the new company to be formed to carry on the undertaking. The capital of the new company will be £1,000,000 in ordinary shares and £900,000 in 5 per cent. debentures.

The tramways in Buenos Ayres, in the half-year ended June 30 last, carried 28 253,543 passengers (compared with 25,732,154 and 20,005,937 in the corresponding half years of 1910 and 1909 respectively). Receipts were $17,368,928 (m.n.) (against $15,391,072 and $14.385,537), of which the Anglo-Argentine Co.'s system accounted for $14,506.036 (against $13,043,699 and $12,622,035) and the Lacroze Co. for $2,392,827 (against $1,965,132 and $1,481,982). The Rosario electric tramways carried 12,352,731 passengers in the same period (against 10,837,143 in the first half of 1910). The output of the Compania Alemana Transatlantica de Electricidad, Buenos Ayres, in the same period was 19,903,981 units for lighting (against 20,010,006 and 14,401,767 in the corresponding half years of 1910 and 1909 respectively), 8,319,006 for power (against 7,595,579 and 5,731,920) and 30,957,038 for traction (against 28,049,270 and 24,304,990).

CITY OF LONDON ELECTRIC LIGHTING CO. (LTD.)—The transfer books and register of members of this company will be closed from 1st to 15th inst., inclusive.

LIVERPOOL DISTRICT LIGHTING CO. (LTD.)—The directors have declared an interim dividend at rate of 4 per cent. for half-year to June 30.

RANGOON ELECTRIC TRAMWAY & SUPPLY (CO.)—This company's gross earnings in July were £7,637. Aggregate from Jan. 1, £58,150.

RIO DE JANEIRO TRAMWAY, LIGHT & POWER CO. (LTD.)—This company's gross earnings in July were £235.457 (increase £34,027. Aggregate from Jan. 1, £1,237,619 (increase £252,871).

SAO PAULO TRAMWAY, LIGHT & POWER CO. (LTD.) (CANADA).—A quarterly dividend of 2½ per cent. on the capital stock, payable on Oct. 2, has been declared.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed Sept. 6 a special settling day in and have granted a quotation to £240,000 4½ per cent. debenture stock of the *Welshach Light Co. (Ltd.)*, and have also granted a quotation to £200,000 5 per cent. mortgage debenture stock of *British Insulated & Helsby Cables (Ltd.)*. The Committee have been asked to grant quotations to £268,235 10s., fully paid, ordinary shares and 80,000 £1, fully paid, 6 per cent. cumulative preference shares (partly in lieu of £5 preference shares now quoted, of the *Hastings & District Electric Tramway Co.*

NOTES.

An Alarming Suggestion.

IT appears that the London County Council are accepting the idea, without any substantial reason for doing so, that some of the recent large fires in the Metropolis were caused by defective wiring; and it is stated that the Council are considering the desirability of making a regulation to the effect that electric wires in all buildings where hotel or sleeping accommodation is available for the public shall be encased in steel tubing throughout. This seems to be another case of legislation by those who are not well acquainted with the technical points involved. Steel tubing is no doubt excellent in many ways, but in some respects wood casing is equally good, so that it is very doubtful if anything is to be gained by stipulating any particular system in general. As a matter of fact, any risk is not as a rule associated with the system used, but is due to details and to those parts of the wiring where the work is not carried out in as thorough a manner as it should be. It would be much more to the point if the Council were to insist upon proper inspection of the work in places of this kind, rather than to make a bye-law which would inflict a deal of hardship without necessarily doing any good.

Gas Progress.

COMPETITION between the electrical and gas industries has been very keen in the past, but it is likely that the future will see even a still more desperate attempt by the latter not only to retain the lighting load which they now possess, but to recapture some of the consumers who have been won over by the advantages of electric lighting. Electrical engineers would therefore be well advised to follow closely any developments, such as new gas lamps of higher efficiency, so that they may be fully informed as to how electrical apparatus compares from the point of view of economy as well as convenience, cleanliness and reliability. A new Nico inverted gas lamp is one of the most recent and, if reports are correct, will shortly be one of the strongest weapons in the hands of the gas industry. This is a low pressure lamp which, it is claimed, gives 42 c.p. per cub. ft. of gas per hour. This figure is stated (by the "Journal of Gas Lighting") to be that of an independent "gas tester." Our contemporary also mentions that the principles of the lamp are not for description at the present stage, but the lamp is already made in sizes of 500 c.p., 750 c.p. and 1,000 c.p., and doubtless it will soon be seen in use. Although the above-mentioned efficiency may have been obtained in a laboratory, and is scarcely likely to be maintained in street or outside illumination, the lamp will apparently prove a strong competitor of electric lamps during the coming lighting season wherever large lighting units are required. The high candle-power metal lamp, however, is likely to hold its own and to become increasingly popular, since its light does not appreciably diminish even after 1,000 hours' use, and no attention whatever is necessary to ensure that the lamp will maintain its rated candle-power.

Tramway Accidents.

THE safety of railway travelling in this country is proverbial, and although slight tramway accidents are of somewhat frequent occurrence there have been but few in the last year or two that have resulted in loss of life. It is, therefore, noteworthy that two serious tramway accidents occurred last Saturday afternoon. The one at Glasgow, due to the illness of a motorman, is, however

Digitized by Google

quite overshadowed by the disaster on the London County Council's system. These tramways, considering their size and the exceptional traffic difficulties, have been comparatively free from serious accidents, but that which occurred last week proved exceptionally disastrous. For the present the cause of the car leaving the rails is shrouded in mystery, and owing to the conflicting evidence as to the state of the rails it is likely to remain so. It is noticeable that the large majority of serious tramway accidents occur at more or less sharp curves in the track; and as the lay-out of such curves necessitates the negotiation of them by the cars at very low speeds it would seem desirable for all curves to be inspected by some authority with a view to possible alteration. Since tramcars have to compete with motor traffic, any reduction in speed would now be a serious handicap; but if present speeds are to be maintained it is essential that great attention should be paid to the maintenance of the track in a clean and good condition.

Production of Light.

THE production of light is one of the most fascinating of subjects, partly because we know so little of the ultimate phenomena underlying some of the processes of production, and partly because of the enormous possibilities that are yet open to the patient investigator. The present methods of producing light are extraordinarily inefficient, and yet during the last few years great advances have been made. The metal filament lamp, the flame arc lamp, the vacuum tube, operated either as a mercury arc or by an electric discharge, all indicate a movement in the right direction. A very great deal, however, yet remains to be done if we are to approach the efficiency of Nature, though certainly the station engineer does not wish this efficiency to be approached too closely. But we do not doubt that there are many investigators who are keenly anxious to produce a truly cold light, either by means of the electric discharge or by means of fluorescence, and thus to emulate the hitherto unrivalled efficiency of the firefly. The engineer wishing to approach this subject from the more theoretical standpoint finds himself at a disadvantage in that the subject in some respects is by no means simple, and further the literature on the subject is more or less scattered, so that it is not easy to find what has been done without spending a good deal of time in looking up various publications. We therefore think that our readers will welcome the series of articles, the first of which appears in our present issue, by Dr. R. A. HOUSTOUN, as they present the subject, although briefly, from many points of view.

The "Telefunken Zeitung."—We have received from Berlin a copy of the first number of this periodical, which is edited by Mr. H. Bredow, and is devoted to the interests of the Gesellschaft für Drahtlose Telegraphie. The present issue contains a photograph commemorative of the visit of the Emperor William to the Nauen station. There is also an historical article on the progress of the Telefunken Co. and other matters of current wireless interest.

Cable Interruptions.	Date of Interruption.
Assab—Perim	July 8, 1909
Latakia—Palura	May 26, 1910
Zanzibar—Mombasa	July 11, 1911
Sabang—Koetaradja	Aug. 18, 1911
Kotonou—Grand Bassam	Aug. 23, 1911
San Thiago—Bathurst	Sept. 4, 1911
Bathurst—Sierra Leone	Sept. 4, 1911

Electric Lighting of Westminster Abbey.—Westminster Abbey, which has been closed since March 31st on account of the Coronation, was opened on Tuesday last for the usual services. The lighting of the nave is now effected by electricity instead of by gas.

Telegraph Union Monument.—"The Times" announces that the International jury have chosen the design submitted by Signor Giuseppe Romagnoli, of Bologna, for the International Telegraph Union monument. The design represents Helvetia seated and having on either side figures representing Trade, Labour and the various professions.

London Electricity Supply Works Survey.—The Chief Commissioner of Metropolitan Police (Sir E. R. Henry) is having a survey made of the electricity supply works, power stations, gas works, &c., within the Metropolitan Police area, with the view of collecting information for the guidance of the police in future industrial disputes.

New Director of the Science Museum.—It is announced that Mr. F. C. Ogilvie, C.B., has been appointed Director of the Science Museum, and will hold this position in addition to his present office of Secretary for the Science Museum and Geological Survey and Museum. Mr. Ogilvie was educated at Aberdeen University and for a time held the position of Assistant Professor of Natural Philosophy, both at that University and at Edinburgh. He was director of the Edinburgh Museum of Science and Art from 1900 to 1903, and principal assistant secretary (Technology and Higher Education in Science and Art) of the Board of Education from 1903 to 1910.

"The Central."—The article of greatest interest in the current issue of this magazine is the first. It is devoted to an account of the life of Prof. Henrici, and is partly autobiographical and partly written by Mr. G. C. Turner. It is illustrated by three excellent photographs of Prof. Henrici at various times of his life, and of the Mechanics Laboratory which he founded at the "Central." A report is given of the complimentary dinner to Prof. Armstrong which was held on May 13th last, and there are also articles on "Lifeboat Launching Slipways"; on "The Training of Alluvial Rivers," by Mr. C. G. Smith, and "Notes upon Modern Simple Span Truss Bridge Construction," by Mr. R. O. Beit.

Deterioration of Insulation on Traction Motors.—The "Engineer" remarks that a tramway or railway motor is usually selected with reference to the work it has to do in propelling the car, with little regard to the extra work which is thrown upon it when braking. It is, therefore, often urged that, since a motor usually operates at a fairly high temperature under normal conditions, the extra load thrown upon it by electric braking is certain to produce more or less rapid deterioration of the insulation. With the latest type of track magnet, however, the current taken from the motors is a very small percentage of that required for rheostatic braking, and the increased heating due to braking with this type of magnet is practically nil. If, in addition, the motor fields are provided with solenoid operated shunts, excessive voltage rises cannot occur, and the usual objections to the use of the motors for electric braking are removed.

Smelting of Pig Iron by Electricity.—An official report on the experiments in the electric smelting of iron ore at Trollhätten has now been published by the Iron Institute of Sweden, which, in conjunction with the Government, provided the money to carry out the experiments on a commercial scale. On the basis of the selling price for the output of the furnace, agreed upon by the committee in charge of the operations, the experimental business was self-supporting, even for the short period of its duration, five months. It is stated that the results obtained warrant the opinion that the question of the economical smelting of iron in the electric furnace has been solved, and that perfection of the methods for handling the gases to secure a more effective circulation, if not their utilisation, will greatly enhance the results already obtained. It is hoped to reach the preliminary estimate of 3 tons of pig-iron per horse-power-year, although the results so far give only

Digitized by Google

2·7 tons. Trials have proved that the product of the electric furnace is as well adapted to the manufacture of steel as is the ordinary Swedish pig-iron.

The Need for Reform in our System of Chemical Training.—In an article on this subject in a recent issue of "Chemical Engineering and the Works' Chemist," the author remarks that too much time is at present given to the acquisition of detail, while too little regard is paid to the real object of scientific education, which is to develop the reasoning powers. Students should be taught chemistry so that they may be able to apply their knowledge intelligently in after-life. To think and to originate are infinitely more important for the man of science than simply to be a master of detail. Some of the cures proposed for this evil are worse than the disease. More attention should be paid to the value of scientific application and less to the results of "cramming." Graduation by research should be made the rule and not the exception, as this method would differentiate between the student who can simply cram facts and one who is capable of applying what he knows to useful purposes. What is above all things necessary, the author concludes, is proper instruction in applied chemistry and encouragement of students to take up applied chemical research. It must be borne in mind, too, that it is not possible to study technical chemistry in a college alone, and that a student should pass a period in works in order that he may gain the all-important experience of the conditions which obtain on a large scale.

Royal Engineer Cadets (2nd London Division).—We are informed that recruits are wanted for this Corps, and great efforts are being put forth to bring it up to its establishment. The Company at present in existence is a Fortress Company, but if the right kind of recruit is forthcoming in sufficient numbers, it is proposed to form a Communication Company. Youths between the ages of 13 and 18 years having a knowledge of electricity or telegraphy should therefore send in their names. The cadets are instructed in all branches of military engineering, and the training and instruction are of a very interesting character for any lad desirous of serving his country.

Cadets transferring to the Territorial Force from their Cadet Corps are excused their recruit drills, and service in a Cadet Unit after the age of 15 counts towards the Territorial Efficiency Medal. Recruits are enrolled between the ages of 13 and 18, and should apply at the Duke of York's Headquarters, Chelsea, S.W., on Monday and Friday evenings between 7:30 and 9 p.m. Full particulars can be obtained from Sergt.-Major G. D. Elms, R.E. (T.), 37, Langthorne-street, Bishop's Park, S.W. Col. Sir Howland Roberts, Bt., V.D., is the honorary Commanding Officer, and the officer in command of the Corps is Capt. Beeman, R.E. The Corps attended the annual training and camp this year with the Royal Engineers, 2nd London Division, at Shorncliffe, from the 7th to the 19th August, and worked with the sappers in building a redoubt and in constructing a trestle and double-lock bridge. The cost of uniform and equipment amounts to about 15s., and there is an entrance fee of 1s. Rifles, bayonets and brown Slade-Wallace equipment are supplied, and remain the property of the Corps.

The Noise of Motor Cars.—During the past few months correspondence has been taking place in several of our daily contemporaries regarding the noise made by drivers of motor vehicles, especially at night. As a result of this agitation, which from our own experience seems to be especially well-founded, the Commissioner of Police of the Metropolis has, with the concurrence of the Local Government Board, issued a circular dealing with the matter. He points out that while it is necessary for all motor drivers to give audible warning of their approach when there is possibility of danger, where the only danger is attributable to reckless speed the practice quickly develops into an avoidable nuisance. Attention is also called to the practice of using a "cut-out" and the employment of siren or multiple horns worked from the exhaust. It is quite certain, he points out, that unless some alteration is brought about by motorists of their own impulse there will be an insistent demand for repressive legislation. In these circumstances the Commissioner of Police thinks it advisable to call upon all owners and drivers of motor vehicles to do what is in their power to reduce the annoyance caused, especially at night, by the excessive use of the horn, or by the use of unsuitable devices, such as those above mentioned, for unnecessarily varying the timbre or intensifying the sound emitted. He feels sure that much may be done by concerted action on the part of owners and drivers of private cars to diminish the nuisance which is now so much complained of. From this circular it is evident that if this plain hint is not sufficient the Commissioner will use his powers to make a bye-law on the subject. The nuisance is of course primarily due to drivers of taxi-cabs and chauffeurs who are freed from the influence of their employers. Since, too, a silent motor-'bus is an assured fact, attention might also be paid to the excessive noise at present made by many of these vehicles.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Dr. R. Beattie contributes an article on "An Extension of Fischer-Hinnen's Method of Harmonic Analysis."

Dr. R. A. Houstoun contributes the first of a series of articles on "Studies in Light Production."

Our special correspondent gives an account of the Papers and discussions at the meeting of the British Association at Portsmouth. Abstracts of the following Papers which were presented at the meetings of the various Sections will be found elsewhere in this issue: "Electric Drives for Screw Propellers," by Mr. H. A. Mavor; "The Origin and Production of Corrugation of Tramway Rails," by Mr. Worby Beaumont; "Recent Developments in Radio-telegraphy," by Prof. G. W. O. Howe. The presidential address of Sir William Ramsay (of which an abstract appeared in our last issue) is discussed in our Leading Article.

The Trades' Union Congress has been held during the week at Newcastle-on-Tyne, and the president, Mr. W. Mullin, referred to the course adopted by the unions when legislation affecting the working classes is in preparation. He remarked that discussions between members of the Cabinet and accredited representatives of the unions had become a part of the regular programme. (We wonder is the same practical course adopted towards the masters). Mr. Mullin referred particularly to the Insurance Bill in this connection. He also referred to the recent series of so-called "strikes."

Shoreditch (London) Council have decided to adopt incandescent electric lighting in place of gas in the portion of their area north of Old-street.

Salford Corporation are recommended to carry out extensions and to effect improvements of their electricity supply undertaking at an estimated cost of £85,350.

The Port of London Authority have decided to provide four electric ambulances for the docks under their control.

An interesting report on methods of charging for electric current at Brighton has been prepared by the engineer and manager, Mr. John Christie. The report recommends the abolition of meter rents and the adoption of a flat rate of charge for all current supplied.

OBITUARY.

T. H. Riches.—We regret to record the death of Mr. Thomas Hurry Riches, locomotive superintendent to the Taff Vale Railway, which occurred at Cardiff on Monday last at the age of 65. Mr. Riches was a past-president of the Institution of Mechanical Engineers and for three successive years was also president of the South Wales Institute of Engineers. He served as chairman of the mechanical engineering section of the Franco-British Exhibition.

H. O. Wills.—We also regret to record the death of Mr. Henry Overton Wills, chancellor of the University of Bristol, which occurred at Kelston Knoll, Weston, near Bath, on Monday last. Mr. Wills took great interest in the formation of the university in Bristol, and went so far in practical sympathy as to subscribe £100,000 towards the project. When the charter was eventually granted Mr. Wills became the first chancellor of the new university.

PERSONAL NOTE.

On Monday Mr. W. Aitken left Liverpool by the s.s. "Megantic" for New York. Mr. Aitken will be absent from England for some time on business and pleasure.

ment small and propeller efficiency as good as is attainable and the quantity of fuel carried small relative to the weight of the machinery, the possible economy in fuel may be insufficient to warrant any increase in the weight of machinery; or, to put the case otherwise, it is advisable to sacrifice economy in fuel to keep down the weight of the equipment—*e.g.*, a vessel running one-day voyages, and burning 50 tons of coal, could not possibly submit to an increase in weight of machinery in excess of the coal-saving, because such increase would increase the displacement, and therefore the power necessary to drive the vessel.

If, on the other hand, the vessel make a 10-day voyage, and the saving in fuel carried amount to 10 tons per day, a considerable increase in weight of machinery might be associated with decreased displacement and a substantial all-round economy.

Various methods of making the required adaptation of generator to propeller are at present under trial. For this, mechanical gearing by toothed wheels or hydraulic transmission may be considered serious competitors with electric transmission, but for large powers it seems reasonable to expect that electric transmission, which is already developed for this very purpose on land, is likely to find an equally useful field where the conditions are such as to require an intermediate device at sea. The cost, weight and efficiency of electric transmission compare favourably in the examples which have been examined with either of the two competing methods.

are attainable in a reciprocating steam engine connected direct to the propeller, and the electric motor is applicable to powers for which there is no possibility of using anything in the nature of reversing gears or clutches.

The property of combining the power of more than one engine for application to one or more propellers is the special feature of the author's inventions as distinguished from the ordinary methods of electrical engineering. Engines of different types, sizes and rates of revolution can have their powers combined without interconnection of their electric circuits, and without risk of mistake or error. An oil engine at 100 revs. per min. may be running the vessel at low speed, and a steam turbine running at 20 times the speed may be jointly applied to the propellers without any complication of the electric equipment. Each unit does its own work independently.

The advantage of such an equipment in vessels which are required to operate under varying load conditions is evident. Without subdivision of the power units the whole of the main machinery must be in motion while the ship is in motion.

At speeds reduced below its normal rate of revolution the turbine is even less economical than the steam engine. Subdivision into high-pressure, low-pressure and intermediate elements has been carried out in certain steam equipments, but this results in a somewhat complicated and inconvenient system of piping, because the steam has to be led from one part of the system to the other across the

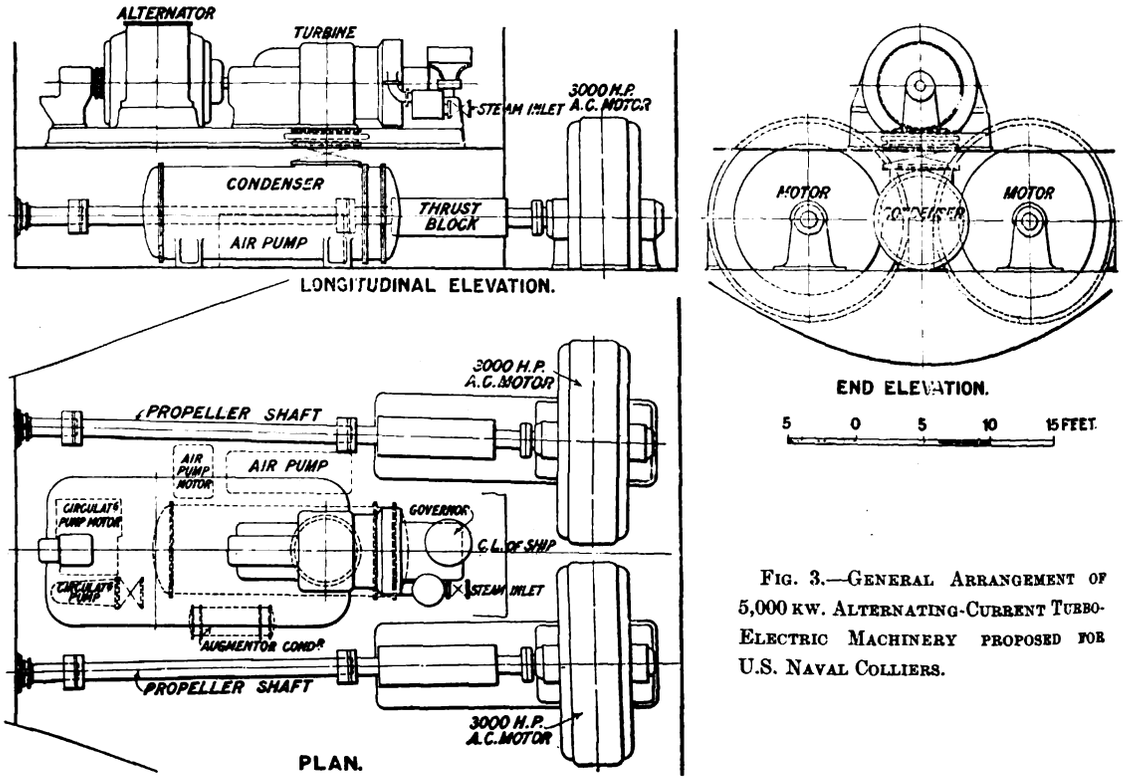

FIG. 3.—GENERAL ARRANGEMENT OF 5,000 KW. ALTERNATING-CURRENT TURBO-ELECTRIC MACHINERY PROPOSED FOR U.S. NAVAL COLLIERS.

There are other important qualifications of electric transmission in which it stands altogether unrivalled. The most important of these qualifications are:—

It provides a ready means of reversing the direction of rotation of the propeller without changing the direction of rotation of the power generator.

The electric transmission also provides means for changing the speed ratio between generator and propeller, so as to permit of the power of the generator being developed under the most favourable conditions at all speeds of the ship.

Lastly, it provides means for applying the power of one or more engines to one or more propellers, so that the power generating units may be so disposed as to give the highest efficiency, and when they are not required they can be stopped. These properties of the electric transmission supply exactly what is required to render steam turbines, and also internal-combustion engines, completely adaptable to the purpose required.

Power generators give their best efficiency when full speed of rotation is maintained, even when running below full power. It is therefore advantageous to keep the engine revolutions within the range of governor control while the required speed change is accomplished by electric combinations.

The properties of the electric motor lend themselves well to the requirements of manœuvring. The rate of reversal is under perfect control. The possibilities of rapid and certain action are more than

vessel. In the electric system each unit can be self-contained, and disposed in the manner best suited to a convenient arrangement of the engine room. The size of the individual units can be adjusted to suit the powers required at the different working speeds, or they may be duplicate and interchangeable.

A few examples of application of the system are here presented, together with a description of a small vessel built to demonstrate and illustrate the principles of operation and to provide experience in the use of the plant. In all cases alternating three-phase currents are used and interlocking devices connect mechanically the main reversing switches with the exciting switches so that no change can take place in the connections while they are passing currents.

DESCRIPTION OF THE TURBO-ELECTRIC STEAMSHIP "FRIEDA" (FOR AMERICAN OWNERS).

This vessel has been specially designed for the transport of bulk freights between the Gulf of Mexico and New York City. The vessel is to be 300 ft. long and will carry a dead weight of, approximately, 5,000 tons at a mean loaded speed of 12 knots at sea.

The propelling machinery is aft, and consists of a turbo-electric outfit for three-phase 50 cycles when running at 3,000 revs. per min. The turbine is supplied with steam at a pressure of 200 lb. per square inch at the stop valve.

This electric generating plant is arranged on foundations on a platform deck in the engine room and the condensing plant in the engine-

Digitized by Google

room hold. The condenser is fitted with a vacuum augmentor, and is suitable for dealing with the full load quantity of steam from the turbine. The vacuum obtained will be 28½ in., with cooling water about 85°F. The condensing plant consists of a vacuum condenser, three-throw air pumps and centrifugal pumps with electric motor drives.

The current is led to a three-phase motor, which is keyed direct to the main propeller shaft, and is capable of developing 1,900 B.H.P. at a speed of about 84 revs. per min. The steam is generated in two Scotch boilers, with Howden's forced draught and liquid fuel burners.

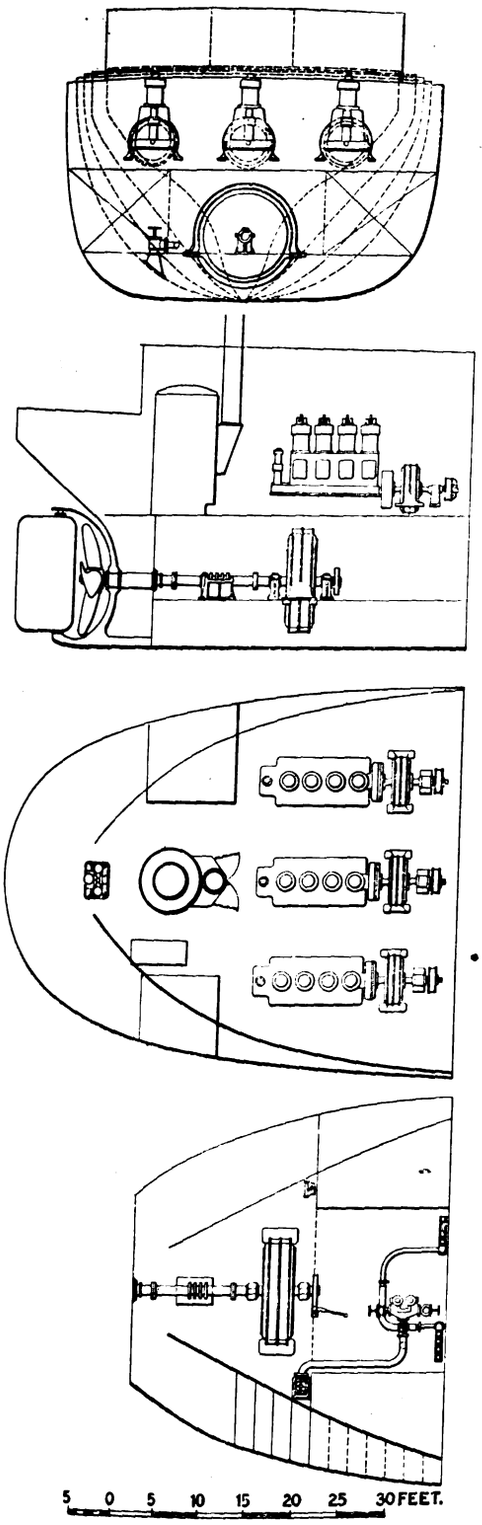

FIG. 4.—PROPOSED ARRANGEMENT OF OIL-ELECTRIC PROPULSION FOR LAKE STEAMER, 250 FT. BY 42 FT. 6 IN. BY 19 FT.

This installation costs and weighs less than the normal equipment. The coal-saving is over 10 tons per day.

The design of the ship itself presents many novel features not germane to the subject under review. This design was prepared by John Reid & Co., 17, Battery-place, New York.

OIL ELECTRIC TANK BARGE FOR CANADIAN SERVICE.

Fig. 4 shows the application of the system to the propulsion of a 245 ft. Canadian canal type tank barge.

The equipment consists of three separate units of Diesel non-reversible oil engines, each capable of developing 200 shaft H.P., and directly connected to an alternating-current generator. The currents from one or all of the units are respectively led to the separate windings of a three-phase motor keyed to the main propelling shaft and operating a single slow-turning screw.

The great advantage and economy of this system consists in being able to run at full power or at one-third power using one or three engines at full-load economy at will, thus providing for an economical operation impossible with any other propulsive system. The fact that non-reversible oil engines are used, running under governor control, greatly simplifies the maintenance and operation.

The control is operated by a low-tension interlocking switch, operated by an ordinary engine-room telegraph stand located in the pilot house, so that the manœuvring of the vessel is at all times in the hands of the navigating officer. This equipment increases the cost of the ship about 10 per cent. above the normal, but the carrying capacity is very largely increased.

MARINE TURBO-ELECTRIC INSTALLATION PROPOSED FOR U.S. NAVY COLLIERS.

The installation illustrated in Fig. 3 shows a marine turbo-electric installation submitted to the U.S. Navy Department for adoption in one of the four large colliers recently given out to contract.

It consists of a steam turbo-alternator of 5,000 kw. capacity with condensing plant; the current is led to two motors, one being keyed to each propeller shaft. The machinery is right aft in the vessel; the steam is generated by Scotch boilers.

The vessels in which it is proposed to instal this machinery are 525 ft. long, and will carry a dead weight of 12,500 tons of coal, at a speed of 14 knots at sea. Here again the cost, weight and economy are better than can be shown with the normal reciprocating-engine equipment.

AN EXTENSION OF FISCHER-HINNEN'S METHOD OF HARMONIC ANALYSIS.

BY R. BEATTIE, D.SC.

Amongst methods of determining the several coefficients in Fourier's expression

$$y = A_0 + A_1 \sin\theta + A_2 \sin 2\theta + A_3 \sin 3\theta + \ldots + B_1 \cos\theta + B_2 \cos 2\theta + B_3 \cos 3\theta + \ldots \quad (1)$$

for a single-valued periodic curve, one of the most useful is Fischer-Hinnen's development of the old principle of selected ordinates.* In order to find the coefficient of a harmonic of the nth order by Fischer-Hinnen's method, $2n$ equi-distant ordinates, spaced a distance π/n apart, are erected, the initial ordinate being at a distance $\pi/2n$ from the origin, or at the origin itself, according as a sine coefficient or a cosine coefficient is desired. The ordinates thus drawn are added together, the signs of all the ordinates of even number being reversed and the mean is taken. Calling S_n the mean of the sine-spaced ordinates, and C_n the mean of the cosine-spaced ordinates, then

$$S_n = A_n - A_{3n} + A_{5n} - A_{7n} + \&c. \quad (2)$$

$$C_n = B_n + B_{3n} + B_{5n} + B_{7n} + \&c. \quad (3)$$

The truth of this result for a particular case is readily apparent from Fig. 1. This figure shows Fischer-Hinnen's construction for determining the coefficients A_3 and B_3 of the curve represented, the sine-spaced ordinates y_1, y_2, y_3, &c., being erected at distances 30, 90, 150, 210, 270 and 330 deg. respectively from the origin, and the cosine-spaced ordinates

* Fischer-Hinnen, "E.T.Z.," Vol. XXII., p. 396, 1901; "Elektrotechnik u. Maschinenbau," Vol. XXVII., p. 335, 1909. y'_1, y'_2, y'_3, &c., at distances 0, 60, 120, 180, 240 and 300 deg. respectively. It is seen that the successive sine-spaced ordinates cut the 3rd, 9th, 15th, &c., sine harmonics at their crest values, which are, of course, alternately positive and negative, whereas they cut the 3rd, 9th, 15th, &c., cosine harmonics at their zero values. Further, the sum of the intercepts of the sine-spaced ordinates with all the remaining harmonics, even or odd, sine or cosine, when taken over a whole period with alternate signs reversed, vanishes. Hence the average value of y_1, y_2, y_3, &c., with alternate signs reversed is equal to $A_3-A_9+A_{15}-$ &c. Similarly, the average value of the cosine-spaced ordinates y'_1, y'_2, y'_3, &c., with alternate signs reversed, is equal to $B_3+B_9+B_{15}+$ &c.

(*a*) Original Curve. (*b*) 3rd, 9th, 15th, &c., sine components. (*c*) 3rd, 9th, 15th, &c., cosine components. (*d*) All the even and all the remaining odd sine and cosine components including the constant term.

FIG. 1.—ILLUSTRATING HARMONIC ANALYSIS OF CURVE BY FISCHER-HINNEN'S 2*n*-ORDINATE METHOD.

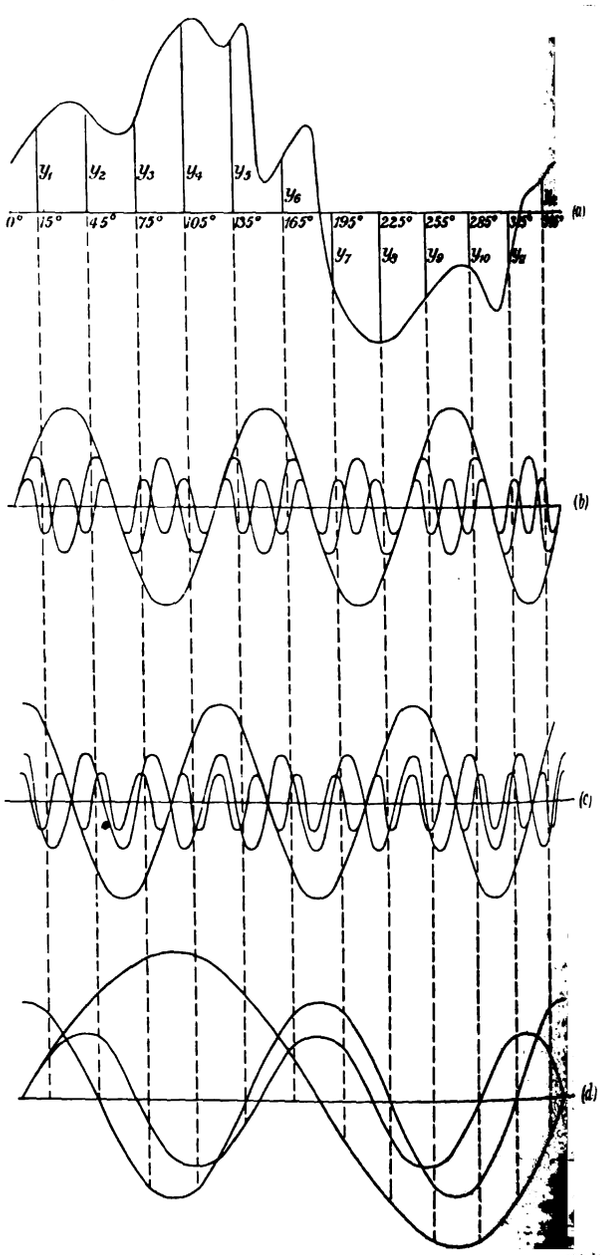
A disadvantage inseparable from Fischer-Hinnen's method is that it does not directly give the value of the harmonic sought, except in the special case where all the odd multiples of that particular harmonic are either absent or negligibly small. In practice, when evaluating higher harmonics, we are often certain, or can safely assume, that this is so, and the method is then specially serviceable. When evaluating lower harmonics, however, the absence of odd multiple harmonics cannot be taken for granted, and a process of elimination must therefore be resorted to. Thus suppose we know that, as in alternating-current wave-forms for instance, there are only odd harmonics present, and also that all harmonics of higher order than, say, the 15th are absent or negligible. We can then write

$$\left.\begin{aligned} &S_{15}=A_{15},\ S_{13}=A_{13},\ S_{11}=A_{11},\ S_9=A_9,\ S_7=A_7,\\ &S_5=A_5-A_{15},\ S_3=A_3-A_9+A_{15},\\ &S_1=A_1-A_3+A_5-A_7+A_9-A_{11}+A_{13}-A_{15} \end{aligned}\right\} \quad . \quad . \quad . \quad (4)$$

from which we readily deduce

$$\left.\begin{aligned} &A_{15}=S_{15},\ A_{13}=S_{13},\ A_{11}=S_{11},\ A_9=S_9,\ A_7=S_7,\\ &A_5=S_5+A_{15},\ A_3=S_3+A_9-A_{15},\\ &A_1=S_1+A_3-A_5+A_7-A_9+A_{11}-A_{13}+A_{15} \end{aligned}\right\} \quad . \quad . \quad . \quad (5)$$

A similar scheme of elimination can be drawn up for the cosine terms.



(*a*) Original Curve. (*b*) 3rd, 9th, 15th, &c., sine components. (*c*) 3rd 9th, 15th, &c. cosine components. (*d*) All the even and all the remaining odd sine and cosine components including the constant term.

FIG. 2.—ILLUSTRATING HARMONIC ANALYSIS OF CURVE BY 4*n*-ORDINATE METHOD.

When there is no certainty that all harmonics above a certain order are either absent or diminish very rapidly in value, Fischer-Hinnen's method, while still applicable, becomes laborious and comparatively useless. Even in these circumstances, however, the scope of the method can, by a simple development, be considerably extended and its accuracy appreciably increased without departing from the general principle involved.

A Modified or 4n-Ordinate Method.—Improvements on Fischer-Hinnen's method may aim at (i) reducing the errors

Digitized by Google

due to accidental irregularities in the curve to be analysed, (ii) reducing the number of included higher harmonics. Both these ends can be attained by increasing the number of ordinates employed. The extent to which the number of ordinates can be increased is limited by the condition that multiplications or divisions must not be introduced further than what is required in averaging ordinates. It is, however, possible to double or even treble the number of ordinates without sensibly departing from this condition.*

Suppose, for example, that we wish to find the coefficient of the nth sine harmonic. Instead of erecting $2n$ equi-distant ordinates, as in Fischer-Hinnen's method, we erect $4n$ ordinates spacing them a distance $\pi/2n$ apart, the initial ordinate of the series being at a distance $\pi/4n$ from the origin. These ordinates we add together, taking them in pairs, and reversing the signs of alternate pairs. That is to say, the signs of the 1st and 2nd, 5th and 6th, 9th and 10th, &c., ordinates are left unchanged, those of the 3rd and 4th, 7th and 8th, 11th and 12th, &c., ordinates are reversed, the scheme of reversal being indicated by $++--++--$&c. The average ordinate obtained in this way when multiplied by $\sqrt{2}$ gives a quantity which we shall denote by S'_n. It is then easy to show that

$$S'_n=A_n+A_{3n}-A_{5n}-A_{7n}+A_{9n}+A_{11n}-A_{13n}-\&c. \quad . \quad (6)$$

To get the corresponding cosine term the ordinates are drawn precisely as for the sine term, with the initial ordinate at a distance $\pi/4n$ from the origin. The only difference lies in the way the ordinates are added up. In doing this the signs of the first and last, 4th and 5th, 8th and 9th, &c., ordinates are left unchanged, whilst the signs of the 2nd and 3rd, 6th and 7th, 10th and 11th, &c., ordinates are reversed, the scheme of reversal being therefore indicated by $+--++--$&c. The average ordinate thus obtained when multiplied by $\sqrt{2}$ we shall denote by C'_n. We then have

$$C'_n=B_n-B_{3n}-B_{5n}+B_{7n}+B_{9n}-B_{11n}-B_{13n}+\&c. \quad . \quad (7)$$

In proof of (6) and (7) it will suffice to take the particular case represented in Fig. 2. Here the ordinates are drawn according to the modified method for determining the 3rd sine component of the curve shown, the ordinates, 12 in number, being spaced 30 deg. apart, with the initial ordinate 15 deg. from the origin. It is seen that these ordinates cut the 3rd sine harmonic and all odd multiples of the 3rd sine harmonic in the same relative position—viz, 45 deg. from the maximum, the 45 deg. being reckoned on the scale of the harmonic considered. It is likewise seen that the sum of the intercepts with these harmonics, taken with signs reversed in pairs according to the scheme $++--++--$&c., is equal to $\frac{12}{\sqrt{2}}(A_3+A_9-A_{15}-A_{21}+A_{27}+A_{33}-\&c.)$. At the same time the sum of the intercepts with all the remaining harmonics, of whatever order or denomination, when taken over a complete period with signs reversed in pairs, is seen to vanish. It follows that $\sqrt{2}$-times the average value of the ordinates y_1, y_2, y_3, &c., with signs reversed in pairs, must equal $A_3+A-A_{15}-A_{21}+A_{27}+A_{33}-\&c$. From this the general result of (6) can readily be inferred, as also, by similar reasoning, that of (7).

It will be observed that the result obtained by averaging ordinates on the above plan still contains all harmonics which are odd multiples of the harmonic sought. These included harmonics have, therefore, to be eliminated by proceeding as in the schemes (4) and (5) already outlined for Fischer-Hinnen's $2n$-ordinate method. Thus, taking the previously chosen case of a curve containing odd harmonics only and none higher than the 15th, we have

$$\left.\begin{array}{l} A_{15}=S'_{15},\ A_{13}=S'_{13},\ A_{11}=S'_{11},\ A_9=S'_9, \\ A_7=S'_7,\quad A_5=S'_5-A_{15},\quad A_3=S'_3-A_9+A_{15}, \\ A_1=S'_1-A_3+A_5+A_7-A_9-A_{11}+A_{13}+A_{15} \end{array}\right\} \quad . \quad . \quad . \quad (8)$$

with a similar scheme for the cosine coefficients.

A Combined or 6n-Ordinate Method.—Taken by itself, the modification of Fischer-Hinnen's method just described has certain minor advantages. These arise in part from the increased number of ordinates employed, which helps to eliminate errors due to accidental irregularities, and in part from the fact that the same ordinates serve both for the sine and cosine components. In practice, however, it does not always lead to results that are conspicuously superior to those obtained by Fischer-Hinnen's $2n$-ordinate method. The improvement hinted at in an earlier paragraph is the outcome of combining the results of the $2n$ and $4n$-ordinate methods.

As has been pointed out, the result obtained in attempting to evaluate a given coefficient, say A_n, by Fischer-Hinnen's $2n$-ordinate method includes the coefficients A_{3n}, A_{5n}, A_{7n}, &c. The result obtained in attempting to estimate the coefficient A_n by the modified method also includes the same coefficients A_{3n}, A_{5n}, A_{7n}, &c., only they enter into the result in a different way. Thus we have

$$S_n=A_n-A_{3n}+A_{5n}-A_{7n}+A_{9n}-\&c.,$$

by the $2n$-ordinate method, and

$$S'_n=A_n+A_{3n}-A_{5n}-A_{7n}+A_{9n}+\&c.,$$

by the $4n$-ordinate method. Hence, by taking the mean of the results of the two methods we can eliminate a large number of the higher included harmonics, and thus obtain a more

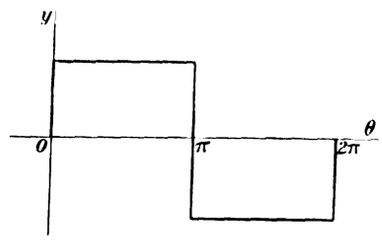


FIG. 3.—RECTANGULAR WAVE SHAPE.

accurate result. Calling the mean of the results for the nth sine coefficient S''_n, where $S''_n=(S_n+S'_n)/2$, we have, in fact,

$$S''_n=A_n-A_{7n}+A_{9n}-A_{15n}+A_{17n}-\&c. \quad . \quad . \quad . \quad . \quad (9)$$

Similarly, if we call C''_n the mean of the results for the nth cosine coefficient, where $C''_n=(C_n+C'_n)/2$, then

$$C''_n=B_n+B_{7n}+B_{9n}+B_{15}+B_{17n}+\&c. \quad . \quad . \quad . \quad (10)$$

Obviously this process (which may be described as a $6n$-ordinate method, since it involves the measurement of $6n$ separate ordinates) gives directly a close approximation to the true value of any harmonic other than the fundamental, since no component of an order lower than seven times that of the harmonic sought is included in the result. To eliminate the few included harmonics that do remain we proceed as before. Thus for a curve containing odd harmonics only, of which the 21st and higher harmonics are assumed to be absent, we have

$$\left.\begin{array}{l} A_{17}=S''_{17},\ A_{15}=S''_{15},\ A_{13}=S''_{13},\ A_{11}=S''_{11}, \\ A_9=S''_9,\quad A_7=S''_7,\quad A_5=S''_5,\quad A_3=S''_3, \\ A_1=S''_1+A_7-A_9+A_{15}-A_{17} \end{array}\right\} \quad . \quad . \quad (11)$$

with a similar scheme for the cosine coefficients.

To illustrate the superiority of the $6n$-ordinate method we may apply it to analyse the rectangular wave-shaped curve of Fig. 3. This curve is known to possess a large number of sine components of odd orders and no cosine components. The amplitude of the components, moreover, decreases very slowly, and the curve therefore affords a severe test of the accuracy of any method of harmonic analysis. Representing the crest value of the curve by 1, its equation as a Fourier series is

$$y=\frac{4}{\pi}(\sin\theta+\tfrac{1}{3}\sin 3\theta+\tfrac{1}{5}\sin 5\theta+\tfrac{1}{7}\sin 7\theta+\&c.).$$

* Fischer-Hinnen's and similar methods of harmonic analysis are examples of approximate integration by averaging a finite number of ordinates. This method of integration and its limitations are discussed by Bruns in his book "Grundlinien des Wissenschaftlichen Rechnens" (Leipzig: B. G. Teubner, 1903). Amongst other examples he considers the evaluation of Fourier's coefficients and (Chapter VII., §§ 85 and 86) gives rules applicable to the general case in which the number of ordinates is made equal to $4m$, where m is any integer. The special advantage of choosing a number of ordinates divisible by 4 is pointed out by Bruns, and much of what follows in the present article might be deduced from his rules by putting m equal to the order of the harmonic sought, or to twice that order.

Digitized by Google

If we analyse the curve by the $2n$-ordinate method we get

$$y=\sin\theta+\tfrac{1}{3}\sin 3\theta+\tfrac{1}{5}\sin 5\theta+\tfrac{1}{7}\sin 7\theta+\text{ &c.},$$

and by the $4n$-ordinate method

$$y=1{\cdot}41(\sin\theta+\tfrac{1}{3}\sin 3\theta+\tfrac{1}{5}\sin 5\theta+\tfrac{1}{7}\sin 7\theta+\text{&c.}).$$

Both these results, which are obtained without having recourse to elimination, are seen to be hopelessly wrong, and equally so for the higher harmonics as for the lower. If, however, we take the mean we get

$$y=1{\cdot}21(\sin\theta+\tfrac{1}{3}\sin 3\theta+\tfrac{1}{5}\sin 5\theta+\tfrac{1}{7}\sin 7\theta+\text{&c.})$$

which for many practical purposes may be accepted as sufficiently correct.

Diagrams for Use with Fischer-Hinnen's Method.—Fischer-Hinnen's method and its modifications have the merit that they can be carried out by the direct addition of ordinates as measured on the curve itself without the use of tables or adventitious aids of any kind. The application of the methods is greatly facilitated, however, by the use of specially prepared diagrams of suitably graduated scales similar to those described by the writer in THE ELECTRICIAN for June 9, 1911.

In the case of Fischer-Hinnen's $2n$-ordinate method, for instance, the diagram for determining an nth sine coefficient would consist of $4n$ equi-spaced vertical scales erected at successive distances of $\pi/2n$, π/n, $3\pi/2n$, $2\pi/n$, $5\pi/2n$ . . . &c., measured from one end of a common base-line. The units of the successive scales would be made equal in length to ± 1, ∞, ∓ 1, ∞, ± 1, ∞, &c., where the upper signs refer to the scales above the base-line and the lower scales to those below. The even-numbered scales are clearly "dummy" ones, and are introduced for the purpose of bringing the diagrams into line with the others.

In the case of the $4n$-ordinate method, the diagram for an nth sine harmonic would, similarly, consist of $4n$ equi-spaced vertical scales erected at distances $\pi/4n$, $3\pi/4n$, $5\pi/4n$ . . . &c., respectively from the end of the base-line. The unit of each scale would be made equal in length to $\sqrt{2}$, the successive scales being marked $++--++$ &c., above the base-line, and $--++--$ &c., below.

In like manner the diagram for determining an nth sine coefficient by the $6n$-ordinate method (which may be regarded as an $8n$-ordinate method with the 4th, 8th, 12th, &c., ordinates omitted) would consist of $8n$ equi-spaced vertical scales erected at the respective distances $\pi/4n$, $2\pi/4n$, $3\pi/4n$, &c., from the end of the base-line. The units of the successive scales would be made equal in length to $\pm\sqrt{2}$, ± 1, $\pm\sqrt{2}$, ∞, $\mp\sqrt{2}$, ∓ 1, $\mp\sqrt{2}$, ∞, $\pm\sqrt{2}$, ± 1, &c., where the upper signs relate to the scales above the base-line and the lower signs to those below.

The investigation of the character of the corresponding diagrams for cosine coefficients may safely be left to the reader.

Twice the average ordinate of a periodic curve, as read on one of the above sine diagrams, would give S_n, S'_n or S''_n according to the type of diagram employed. Diagrams of this kind adapted to Fischer-Hinnen's method or its modifications will, on comparison, be seen to be but particular cases of the general "reciprocal-sine" and "reciprocal-cosine" diagrams described in THE ELECTRICIAN article just referred to. The general diagram passes into the particular whenever the number of scales which it contains is made some fixed multiple (such as 4 or 8) of the order of the harmonic for which the diagram is constructed. Thus the diagram for a $2n$-ordinate Fischer-Hinnen method is a $4n$-ordinate reciprocal-sine diagram constructed by dividing the base-line into $4n$ equal parts and erecting scales at the several points of division. If instead of erecting scales at the points of division we erect them midway between the points of division, we get a diagram for the $4n$-ordinate modification of Fischer-Hinnen's method. So, also, a diagram for the $6n$-ordinate modification of Fischer-Hinnen's method is a reciprocal-sine diagram constructed by dividing the base-line into $8n$ equal parts and erecting scales at the points of division.

It must not be forgotten that reciprocal-sine diagrams with a fixed number of scales occasionally assume the special forms indicated above. Thus, in applying a 24-ordinate reciprocal-sine diagram to determine a 3rd harmonic we are actually using an $8n$-ordinate diagram (or what we have elsewhere called a $6n$-ordinate method of the Fischer-Hinnen type), and therefore the 21st, 27th, &c., harmonics are included in the result which is thus inaccurate to that extent. Again, in applying a diagram with the same number of ordinates to evaluate a 6th harmonic, we are, in fact, using a $4n$-ordinate Fischer-Hinnen method, and the result must contain the 18th, 30th, &c., harmonics. In the practical application of fixed ordinate methods the risk of error from this cause can be largely minimised by employing a sufficient number of ordinates.

Alternative Methods.—The preceding discussion does not pretend to be exhaustive, and certain alternatives to the methods described are possible. Thus we might devise an alternative to the $4n$-ordinate method by erecting ordinates y_1, y_2, y_3, &c., at the respective distances $\pi/6n$, $5\pi/6n$, $7\pi/6n$, $11\pi/6n$, $13\pi/6n$, &c., from the origin. Twice the average of these ordinates with signs reversed in pairs according to the scheme $++--++$&c., gives $A_n+2A_{3n}+A_{5n}-A_{7n}-2A_{9n}-A_{11n}+A_{13n}+$ &c. By taking the arithmetical mean between this result and that given by Fischer-Hinnen's $2n$-ordinate method (thus utilising $6n$ separate ordinates), we obtain $A_n+\frac{1}{2}A_{3n}+A_{5n}-A_{7n}-\frac{1}{2}A_{9n}-A_{11n}+A_{13n}+$&c. To get the corresponding cosine terms a new set of ordinates y'_1, y'_2, y'_3, &c., must be erected at successive distances $\pi/3n$, $2\pi/3n$, $4\pi/3n$, $5\pi/3n$, $7\pi/3n$, &c., from the origin. Twice the average of these ordinates with signs reversed in pairs according to the scheme $+--++--$&c., gives $B_n-2B_{3n}+B_{5n}+B_{7n}-2B_{9n}+B_{11n}+$ &c., and by combining this with the corresponding result obtained by the $2n$-ordinate method we have $B_n-\frac{1}{2}B_{3n}+B_{5n}+B_{7n}-\frac{1}{2}B_{9n}+B_{11n}+$ &c.

Another way of treating the ordinates drawn as indicated in the last paragraph is to average y'_1, y'_2, y'_3, &c., with signs reversed in pairs according to the scheme $++--++$ &c. This average, when multiplied by $2/\sqrt{3}$, gives $A_n-A_{5n}+A_{7n}-A_{11n}+A_{13n}-$&c., or, combined with the $2n$-ordinate method so as to utilise $6n$ separate ordinates, $A_n-\frac{1}{2}A_{3n}+\frac{1}{2}A_{9n}-A_{11n}+A_{13n}-$&c. Similarly, $2/\sqrt{3}$ times the average of y_1, y_2, y_3, &c., with signs reversed in pairs according to the scheme $+--++--$&c., gives $B_n-B_{5n}-B_{7n}+B_{11n}+B_{13n}-$&c., or, combined with the $2n$-ordinate method, $B_n+\frac{1}{2}B_{3n}+\frac{1}{2}B_{9n}+B_{11n}+B_{13n}+$&c.

Evidently both of the "combined" or $6n$-ordinate methods thus obtained are inferior to the $6n$-ordinate method previously described, since the results they give contain a larger number of included harmonics. In this respect the second of the alternative $4n$-ordinate methods is, however, superior to the $4n$-ordinate method referred to in an earlier part of the article, as also to Fischer-Hinnen's $2n$-ordinate method. Thus the ascending order of accuracy as estimated by the number of included higher harmonics is (i) Fischer-Hinnen's $2n$-ordinate method, (ii) the second of the alternative $4n$-ordinate methods, (iii) the $6n$-ordinate method first described.

THE ORIGIN AND PRODUCTION OF "CORRUGATION" OF TRAMWAY RAILS.*

BY W. WORBY BEAUMONT.

Summary.—The author calls attention to the various stresses which are set up in free flat bars of iron and steel when subjected to rolling or hammering, and that this originates on the upper surface of the rail a condition of intense compressive stress, tending to produce a modification of form. The results of tests made on the L.C.C. tramways and other systems are given.

Few of the phenomena of the behaviour of materials employed in tramway construction have given rise to so much enquiry, speculation and diversity of opinion in the last few years as the phenomenon known as "corrugation" of tramway rails.

The rapid spread of its occurrence in nearly all towns with heavy tramway service has directed anxious attention to the discovery

* Paper read before Section G (Engineering) of the British Association at Portsmouth.

Digitized by Google

of its cause, and much has been written concerning it, and some experimental investigations have been made. Unfortunately, the indoor experiments have seldom been conducted with apparatus or under conditions which simulate those of the tramway itself.

On the other hand, the observations which have been made by many on the rails themselves have led to every possible variety of interpretation of the cause of corrugation, largely because of the apparent contrariety of its occurrence and non-occurrence.

The author had commenced the preparation of an index to the Papers and articles which have appeared in this and other countries during the past five years, but it was soon found that this would be of intolerable length, and after all of but little service. The "Proceedings" of the Institution of Civil Engineers provide abstracts of Papers too numerous to mention; the Institution of Electrical Engineers has dealt with the subject; the Municipal Tramway Association and the Tramway Congress hardly ever meet without dealing with the subject; the Tramways and Light Railways Association Official Circular and "Journal" for some years has been crowded with corrugation inequalities and vagaries, and lately a Joint Committee of the two Associations—the Municipal Tramways Association and the Tramways and Light Railways Association—has been working on the subject. To the proceedings of this Committee the author has contributed, and had previously dealt with the subject elsewhere. Foreign authors have contributed largely, and a report by a Committee consisting of the managers of nine Continental tramway systems, one British professor of engineering and the secretary, was discussed at the International Tramway Congress held in Brussels in 1910.

One of the recent and most useful reports on the subject (although some judicious analysis of the facts presented is required) has been prepared as a provisional report by a Committee of the technical department for railway construction and exploitation of Amsterdam, including Messrs. J. Schrooder van der Kolk, M.P., Mass Geesteranne and T. E. van Putten. And more recently a Paper by Herr Von Borries, of much merit, has been published.

Having given some attention to all this literature of this particular

FIG. 1.

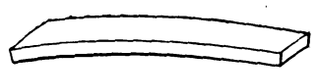

FIG. 2.

engineering ailment, and being aware of the indecision that still exists in the minds of many upon it, the author now ventures, at more length and with the object of greater precision, the explanation he has on previous occasions attempted to convey.

The subject has hitherto been treated mainly from the general point of view suggested by the practical experience of the tramway manager and engineer, and has seldom attracted or received the considered reasoning conjointly of the mechanic and the physicist. It is, however, one which in a marked degree demands the patient application of the attributes of both, and in this Paper I may repeat the words of Mr. H. R. A. Mallock,* and say "it is often useful to have a simple, even if incomplete, theoretical treatment of a subject provided that the theory is correct as far as it goes, and is kept within bounds by comparison with actual observations."

In a surface of a homogeneous solid under compressive stress in orthogonal directions in the plane of the surface, every particle tends to cause every particle surrounding it to recede in every direction.

If one surface of a free flat bar of steel or iron, as Fig. 1, be rolled or hammered, the material of that surface is subjected to a compressive stress. Of this stress it is relieved in the direction of length of the bar so far as the stress is no greater than that which is necessary to bend the bar, and cause it to keep the bent form of Fig. 2.

If of wrought iron, the molecular surface stress will in part be relieved by flow of the material or detrusion along the edges of the hammered surface, and the longitudinal bending be less than if the bar be of rail steel, in which the detrusion will be less.

If of cast iron, the surface compressive stress will accumulate and the bar will be bent by it; but the accumulation of stress reaches an early limit, as it sooner exceeds the limit of cohesion between the surface and subjacent material. The result is that, with cast iron, surface crumbling occurs and limits stress accumulation. It does, however, become sufficient to permit its use as a means of straightening cast-iron coping plates and the like if slightly curved when taken out of the sand.

If when a bar has been bent by surface compression of one side, it be forcibly straightened, the compressive stress will be increased, and a tensile stress impressed on the opposite side sufficient to eliminate the difference of dimension of the two sides caused by the compression. To remove the difference permanently the stress on the uncompressed side must reach the character of strain, equally distributed throughout the whole length of the bar. At the same time an increase is made in the compressive stress on the rolled or hammered surface. This cannot be relieved by a single pucker or extrusion of the surface about the centre of length of the bar, as the stress is uniformly distributed. Hence, at distances apart (or pitch), depending on the elastic and cohesive properties of the material, there will result incipient surface crumblings or corrugations, as shown exaggerated in Fig. 3.

The bearing of this fact on the tramway or railway rail will appear hereafter, but here it may be observed that the stresses in a bar which is bent by compression of one side and caused to retain the bent form by that resident molecular stress, is not in the same condition as to stress throughout its structure as a similar bar bent and maintained in a bent form by mechanically imposed distributed load.

FIG. 3.

In the bar bent by compression of the material on one side there is molecular tensile stress immediately below the hammered surface. The compression differentiates in intensity from the surface to a zone or couche under tensile stress resulting from the molecular cohesion which has prevented the compressed and extended surface from separating itself by shear. Below this, tensile stress differentiates into a neutral zone and therefrom into the compressive stress which remains resident in the bar so long as it is bent by these internal forces.

In a surface such as that of an ironplate which has been rolled or hammered on that surface only, the particles of the hammered surface are, as previously mentioned, restrained by cohesion of and with the subjacent particles, which are less and less under compression as they are remote from the compressed surface film.

If any two points, a, b, or a', b', Fig. 4, be taken in such a surface film, it will be seen that all the particles round each point press towards it with forces proportional to some function of their respective distances from such points. In a line drawn from a to b, or a' b', there are, therefore, equal and opposite forces tending to separate those points, and when their amount exceeds the elastic resistance of the material, deformation or crushing or crumpling

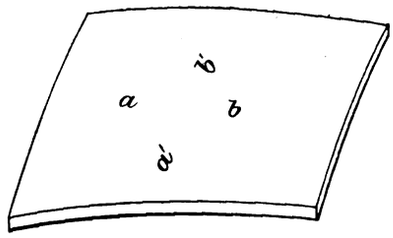

FIG. 4.

must occur, if change of form of that of which the surface is a part be restrained. If the surface be that of a deformable plate, then the forces are in part relieved by bending the plate in orthogonal directions. It is not necessary here to determine the distance between a and b at which any given material will reach the yielding point, or at which the accumulated forces will be sufficient to cause either the bending of a plate or give rise to destructive stresses in any other form of which the compressed surface is part.

To this a return may be made later, but here it is sufficient to repeat that it will be dependent upon the relation between the elastic resistance of the material to compression and its elastic tensile strength and its hardness.

In dealing with these stresses as occurring in practice, and in such forms as those of a railway or tramway rail, it will be seen from the foregoing that the values of the stresses in orthogonal directions soon reach inequality, because while they become cumulative in the direction of length of the rail, the distance transversely separating the points a and b earlier reach the limits of dimensions at which the forces can arise, because relief of the stresses is found in lateral deformation or detrusion at the rail edges, as in Fig. 5.

There is a further view of the physical conditions to be considered, which under the mechanical conditions of the rolling of a wheel on

* "Proc." Inst. Civ. Eng., Vol. CLXXVIII., 1909.

Digitized by Google

the plane surface of a rail under pressure greater than or approaching its elastic resistance gives rise to that which results in what is known as corrugation.

A loaded circular surface, as of a roller or wheel resting upon a deformable straight plane surface, has but a line contact with that surface until either or both the circular and flat surfaces of contact are so deformed by loading the roller as to increase the area of contact. The deformation will continue until the resistance to deformation equals the force producing it. If the materials of the two surfaces be equally resistant, the circular surface will be flattened and the flat surface will be depressed or indented. If the roller be of the more resistant material, the deformation may be chiefly in the material of the flat surface. If the roller be made to roll along the surface which it can so deform it presses before it a wave of deformation. The depression giving rise to this wave may (as in the case of the tramcar wheels and rails) approach or exceed the limit of elastic deformation of the material of the rail. When this is the case, continuation of the movement of the roller upon the surface demands

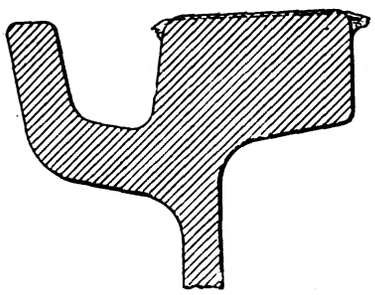

FIG. 5.

the translation of the crest of the wave, and this would involve the destruction of the cohesion between the rolled compressed surface wave crest and the material supporting it and of which it is a part. The result, therefore, is that tensile stress arises *pari passu* with the wave formation between the wave particle and the subjacent particle of the material supporting it, and the point is reached at which the tensile resistance to the increase of the wave height prevents further increase. The roller then must rise upon the minute crest, and in doing this with its heavy load upon the extremely small area compresses it to extreme hardness.

The roller (wheel) in its continued progress repeats the process and continuously adds to the rearward dimensions of the hardened spot.

The foregoing then shows that the rolling and hammering of the upper surfaces of a rail originate a condition of intense compressive stress, the elimination of which produces, or tends to produce, modification of form. It also shows that areas of maximum compression are originated at points separated by distances which are determined mainly by the relation between compression resistance and elastic strength of the material rolled, but in part by the relative hardness of the roller and rail and by the mechanical conditions which affect the area of the roller and rail contact.

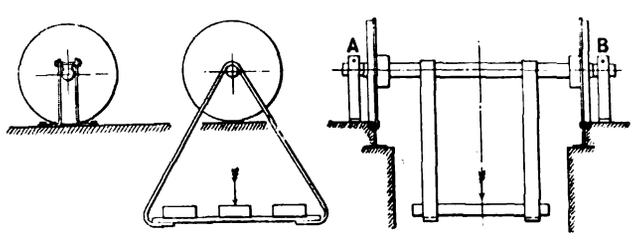

FIG. 6.—AREA OF CONTACT OF TRAMCAR WHEELS ON RAILS.
(Experimental Apparatus.)

The area of contact of hard tyre tramway wheels on steel rails is very small—is less than on ordinary railway wheels. On the latter it has been found to vary, with wheels 4 ft. 6 in. to 5 ft. in diameter, and carrying a steadily applied static load of from 12,000 lb. to 14,000 lb. per wheel, from 66,000 lb. to 48,000 lb. per square inch of contact area. The minimum and maximum areas of a larger number of observations gave loads per square inch of contact area of from 26,607 lb. to 85,961 lb. This, however, was the minimum pressure, as it was taken with engines standing on a level rail and the wheel gently lowered on to it. With an engine moving at speed and heeling over as on curves, this pressure would be much greater. It must further be noted that the central part of the area of contact would be much more severely pressed than the borders of the area.

By the courtesy of Mr. A. L. C. Fell, M.I.E.E., the author has been enabled to give measurements made at his request of the pressure of the wheels of a standing car on rails of standard type. These measurements were made by loading the axles of the larger and the smaller wheels of the bogie of one of the large standard London County Council double-bogie trucks.

For the purpose of the experiments, a sling was made as shown in the diagram Fig. 6. This consisted of flat bars to which were bolted three pieces of timber on which the load was placed. The rails were carefully cleaned and the wheels turned to the correct standard taper, but with a finer cut than that usually adopted in practice.

The load used was as follows in each case :—

Driving wheels, 31 in. diameter, 6 tons.
Pony wheels, 21·56 in. diameter, 3·25 tons.

These weights approximate closely to the actual weights on a standard bogie car when loaded.

The wheel on the side marked A, *see* Fig. 6, was on the rail where it was continuously supported. On the side marked B the wheel rested immediately above the centre of a pier 14 in. wide, where the rail was not quite so rigidly carried. The diagrams obtained, marked 1 in Fig. 7, were slightly larger on this side.

The rails showed very little sign of wear, and the experiments were made at the end of a shop which has not been very much used. At each end of the axle a guide bracket was fixed to the ground, as shown in Fig. 6; between these brackets and the axle journal boxes pieces of wood were fixed to prevent lateral movement.

The axle was lifted at the extreme end by means of a jack, and lowered carefully on a piece of tissue paper on thin carbon paper placed on the rail under the wheel. The impressions made are shown by the diagrams herewith (*see* Fig. 7).

The rails were of British standard hardness, and the tyres were manufactured to specification, for the following extract from which the author is indebted to Mr. Fell.

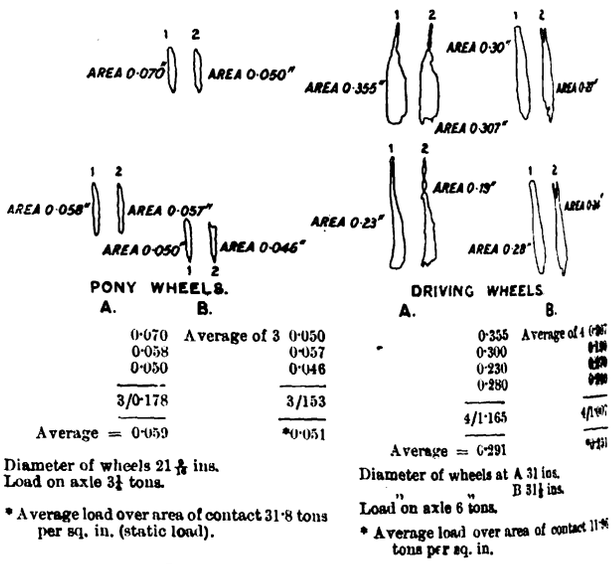

FIG. 7.—DIAGRAMS OF CONTACT AREAS.

Tensile strength not less than 55 and not more than 70 tons per square inch, minimum elongation of 11 to 8 per cent. in 2 in., and of the following composition :—

Carbon	0·65 to 0·75 per cent.
Silicon	0·32 "
Manganese	0·6 to 0·8 "
Sulphur	0·035 "
Phosphorus	0·035 "

The tyres are thus of harder material than the rails, which have 0·40 to 0·55 per cent. carbon.

The areas of contact carefully measured from these diagrams are given on the drawings accompanying this Paper, the areas and pressures given being those obtained from the smaller diagrams marked 2 measured on the inner edge of the black lines made by the carbon paper. The loads given per square inch are the average loads over the whole area of the diagram when the tyre had pressed into the rail, and the tyre itself also microscopically deformed until the area of support given was obtained. The pressure per unit of area in the centre of the area of support would, of course, enormously exceed this average, and I estimate the maximum static pressure to be not less than 35 tons per square inch under this driving wheel. When the car is running at ordinary speeds the pressure would rise to not less than double this as impact pressure, and when the car runs at speed round curves, and the greater part of the load with the heeling over of the car is visited on the wheels on one side, the pressure might easily reach at least 100 tons per square inch.

Digitized by Google

On the pony wheels the average pressure of the whole area of contact under static loads reached 31·8 tons per square inch. The maximum pressure in the centre of area of contact was probably not less than 50 tons. This, with the car running at ordinary speeds, would probably reach 90 tons per square inch, and when running at speed round curves and the car heeling over so that the greater part of the load rested on the wheels on one side, the maximum pressure would probably reach 120 tons per square inch.

It is clear, then, that the pressure per unit of area much exceeds the limit of elastic compression of the material of the average rail, and that flow or deformation would occur were it not that the area pressed is supported by the surrounding material and held *encastrée*, so that flow cannot occur. One result of this is the detrusion of one or of both the rail edges, as shown by Fig. 5, by which cumulative

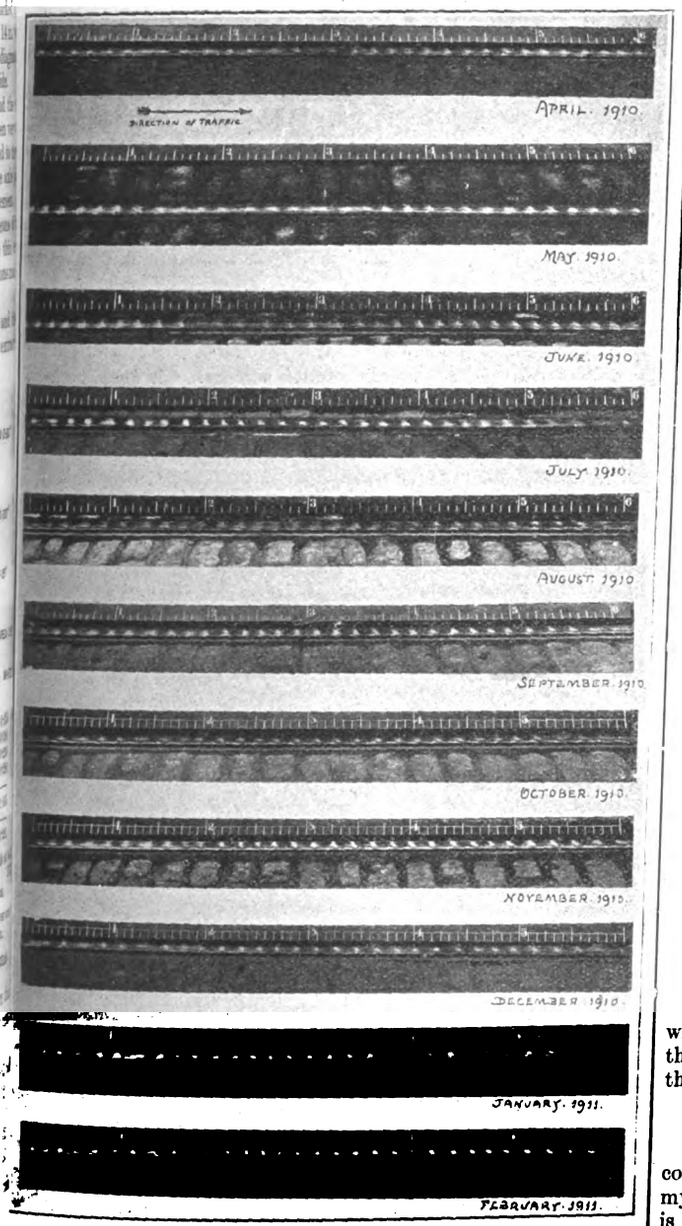

FIG. 8.—LEEDS CITY TRAMWAYS.—PARK LANE.
38 ft. 6 in. past pole 20. Outgoing track. Outer rail. Straight track. Down gradient 1 in 70. Pitch of corrugations, 2 in. In use 10 years. Section No. 6, L.S.W.

disruptive forces are in part dissipated and the extruded material on the groove edge of the tread is removed by the car wheel flanges. Another result is corrugation, and a third is the minute crumbling and pitting of the rolled surface.

Under some circumstances and conditions corrugations may decrease as the raised hardened surfaces approach by lengthening; and as corrugation and the surface become more uniform by the removal of surface material by crumbling or minute flaking, especially of the harder rails with up to 0·66 of carbon, which best resist the causes of corrugation. The removal of corrugations, however, by grinding only prepares the rail surface for quick recommencement of corrugation or for lengthening the hardened part of the corrugations.

If the preceding be accepted as the origin and production of corrugation, then the question remains, What are the remedies? The mechanical originating conditions being the weight on the wheels and the increase of that weight, more especially on outside curves by car heeling at the higher speeds, then :—

The first and most effective remedy is the reduction of the great destructive weight on the wheels of the modern car.

The second is the use of larger wheels than can be used with the present design of car.

The third is the maintenance of moderate speeds; of much lower speeds than are common on curves even those of large radius, and moderate speeds on lines that may be classed as straight, but which have such departure from straightness as will encourage boxing or wandering of the cars from side to side.

Fourthly, the use of harder rails than the hardest at present employed.

The reduction of weight is possible, the reduction of speed is possible, the use of larger wheels is possible with future cars, and the use of harder or more resistant rail materials may be possible, but they would have to be produced by methods more costly than those now adopted. The remedies will involve modifications in the views at present prevalent as to the place, purpose and working of tramway services; but even the most ardent advocates of tramway ubiquity

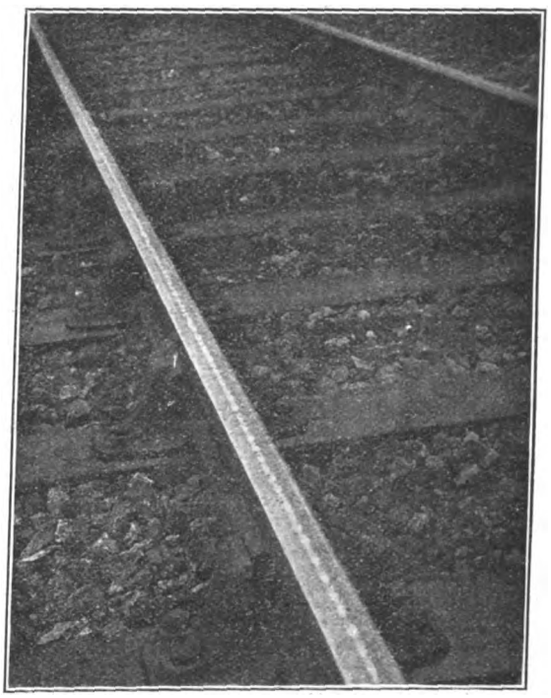

FIG. 9.—ON MIDLAND RAILWAY.—SHEFFIELD.
Straight track. Falling gradient of 1 in 100.

will ultimately be constrained to admit that tramways, like all other things that have and offer desirable ends and convenience, have also their economic and expediency limits.

ADDENDUM.

The occurrence of corrugation of electric tramway rails, as recorded by many tramway engineers and managers, and as found by my own observations extending over some years at home and abroad, is everywhere associated with the following broad generalisations of facts :—

1. That it occurs on straight lines and on curves.
2. That it is most prevalent and generally commences on curves of large radius—flat curves.
3. That it never or rarely occurs on curves of small radius—*e.g.*, from 40 ft. to 80 ft.
4. That on hills, and especially on slight gradients, it is most prevalent on the down line.
5. That its occurrence as to date or length of time after laying the rails varies broadly with (*a*) the position of the rail on straight or flat curve or down gradient, (*b*) the frequency of the service, (*c*) the mechanical properties and composition of the rails, as shown by more or less outer edge detrusion.
6. That it occurs with all types of truck.
7. That it is most prevalent where the speeds are highest.

Digitized by Google

The general appearance of corrugated rails is known to all who are interested in the subject, and photographs showing corrugations in various stages of growth in many towns might be shown. The author is enabled, by the courtesy of Mr. J. B. Hamilton, general manager of the Leeds tramways, to show photographs of three sets of 33 rails in that city. These photographs show rails which have been in use from 4 to 13 years on straight track. Those which have been in use 13 years are on the level, those of 10 years (*see* Fig. 8) are on a gradient of 1 in 70, and those which have been in use four years are on a gradient of 1 in 50.

A small photograph, Fig. 9, is exhibited of a rail in a straight piece of track on the Midland Railway, Sheffield, on a falling gradient of 1 in 100. This shows a much worn rail, with the bright hard spots about the centre of the tread, and shows that what is called corrugation is not confined as to nature of origin or production to street tramway rails, although it is necessarily much more general and severe on tramways and other rails where heavy vehicles with small wheels and high speeds are used, as, for example, on some of our tube lines and the Metropolitan of Paris.

RECENT DEVELOPMENTS IN RADIO-TELEGRAPHY.*

BY G. W. O. HOWE, M.SC.

Summary.—The author first discusses the difficulties experienced in wireless transmission due to interferences, atmospheric disturbances, &c. He then considers recent developments for minimising such interference and improving the conditions, dealing firstly with the transmitting apparatus, and secondly with the receiving apparatus.

During the last two or three years the number of radio-telegraphic installations has increased enormously both on land and sea. This increase has not been due so much to any new discovery or striking improvement as to several instances in which radio-telegraphy prevented what might otherwise have been terrible calamities at sea.

The total number of ships of the mercantile marine fitted with Marconi apparatus at the end of 1907, that is, after seven years of development, was 140; at the end of 1908 the number was 220; at the end of 1909 it was 330, while at the close of last year it had risen to 510. In addition to the mercantile marine, practically every ship in the British navy has been fitted with Marconi apparatus.

The Telefunken Company, of Berlin, carried out 106 installations last year, bringing the total number of stations using their apparatus up to nearly 1,000. About 500 of these are warships, principally German and Russian, while 100 are portable military sets. Excluding German boats, only 13 ships of the mercantile marine are fitted with Telefunken apparatus.

Marconi's earliest experiments were made in 1895–1896 and now, after 15 years, every passenger ship of any magnitude has its wireless installation as a matter of course. There is every indication that very soon practically every ship will be so equipped. Some of the trawlers of the North Sea fishing fleet have recently been fitted with Telefunken apparatus with a range of about 100 miles. These boats receive the weather reports sent out daily from the coast stations and are thus able to warn the fleet of approaching storms.

As was recently pointed out by Mr. Bradfield of the Marconi Company the increase in the number of installations will probably be cumulative, since each installation on land or sea increases the value of the service to every ship making use of it. There is, however, another aspect to which attention should be drawn, and that is, that the troubles due to interference between stations working simultaneously will also increase cumulatively. These troubles promise to become of the gravest importance in the immediate future.

Before one can appreciate the recent developments in the apparatus, one must know something of the difficulties experienced in carrying on radio-telegraphic communication. The nature of the telegraphic service which may be required of a station is very varied. A station may have to work with only one other station and never send to, or receive from, any other. This is practically the case with the trans-Atlantic stations. A station may correspond with a limited number of stations with definite and well-known characteristics as in the case of the mail-boats running between England and the Continent. On the other hand, a station may have to work with all comers.

One can easily see that apparatus which might be eminently suitable in one case would be very unsuitable in the other. Stations in the first category can use uncommon wave-lengths and thus free themselves, to a large extent, from interference from other stations, besides being able to use a large amount of power without causing interference. The Marconi trans-Atlantic stations in Ireland and Nova Scotia use a wave-length of over 6,000 metres (50,000 c. per second) and are thus free from disturbance from ships which generally use 300 to 600 metres.

Stations of the third class, on the other hand, should be able to call, or be called up by, ships or land stations, fitted with any make of apparatus covering a wide range of frequency.

To appreciate the difficulties due to interferences one has only to consider a station on the Kentish coast, with half-a-dozen ships within range all wishing to communicate with the coast station. They can only communicate one at a time, and each operator naturally tries to "catch the speaker's eye," which in this case is the coast operator's ear, by calling often and loudly, notwithstanding any regulations to the contrary. The same thing may be going on at other coast stations on both sides of the Channel. In addition to this we have English and French warships and dockyards working at the same time. If every station or every ship had a different wave-length it might be possible to tune the others out to a certain extent, but for the sake of uniformity and convenience in working, the majority of stations have about the same wave-length, so that when one is tuned to the desired station, one is also tuned to the disturbing stations. The result is that one station tries to shout the other down and the successful working of all the stations is greatly hindered. At the City and Guilds College in South Kensington one of the aerials is a single wire 260 ft. high and with this one can sometimes hear half-a-dozen stations sending simultaneously at approximately the same wave-length, making it absolutely impossible to read any one of them.

Apart from all this, there are the atmospheric disturbances, which vary very much from time to time. One station receiving from another a thousand miles away will certainly hear every lightning flash over a large part of the earth's surface. These atmospheric disturbances are often strong enough to make working impossible over any but very short distances, even when the weather conditions locally look ideal.

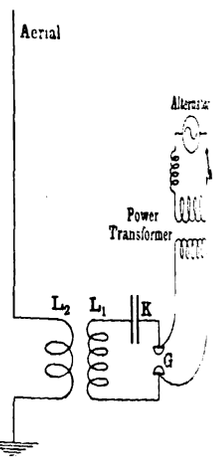

FIG. 1.

Whether one can receive or not in spite of these atmospheric disturbances depends on the loudness and nature of the signals, so that one can become more and more independent of the atmospheric conditions by increasing the power employed and by making the signals easily distinguishable from the sounds caused by the disturbances.

Recent developments in the sending apparatus have been largely directed towards obtaining freedom from interference. This has been sought in two ways: Firstly, by sending out well-sustained trains of waves of one definite frequency, giving sharper tuning, and secondly, by giving the signals a high musical pitch, easily distinguished from the crackling noises caused by atmospheric disturbances and also from other stations having notes of a different pitch. The spark-gap must be so designed that these characteristics are retained when very large powers are employed. A spark-gap may work excellently when the power is small, but fail entirely when the power is increased. Absolute reliability and constancy are of far greater importance than efficiency, although any improvement in the latter is to be welcomed, not so much for the saving of power as for the reduction in size and cost of the apparatus.

Fig. 1 may be taken to represent diagrammatically the sending apparatus of almost every system, by whatever name it may be called. In all except the smallest installations, the sparking coil with hammer or mercury break has been replaced by an ordinary power transformer supplied with alternating current, as shown in the figure. The coils L_1, L_2 constitute an air-core Tesla transformer of few turns. It is sometimes connected as an auto-transformer, *i.e.*, with a single winding tapped off at different points, but this alters nothing so far as the principle is concerned. If coil L_2 is far removed from coil L_1, each discharge of the condenser K across the gap G will cause a damped oscillation in the primary circuit GKL_1, as shown in Fig. 2. The rapid damping is mainly due to the dissipation of energy in the spark-gap. The time, T, of a complete oscillation depends only on K and L_1 and is usually about 1/500,000 second, corresponding to a wave-length in space of 600 metres. All the energy stored in the condenser at the moment of breakdown is dissipated as heat in the gap and in the remainder of the oscillatory circuit. It is seen that the oscillatory disturbance caused by one spark lasts about 1/50,000 second. Nothing further happens until the condenser is charged up

* Paper read before Section G of the British Association at Portsmouth.

Digitized by Google

to the same potential difference as before. If the gap is made so long that the spark can only just jump it, the next spark may not occur until several half-cycles of the alternating supply have passed, the voltage across the secondary of the power transformer gradually building up due to resonance. This resonance is obtained by adjusting the speed of the alternating-current generator. The result will be that, with an alternating-current supply of 50 cycles per second, the sparks may occur at intervals of 1/20 to 1/30 second (Fig. 2). This is the method which was largely used two or three years ago and which is still used by the Eiffel Tower and many other stations.

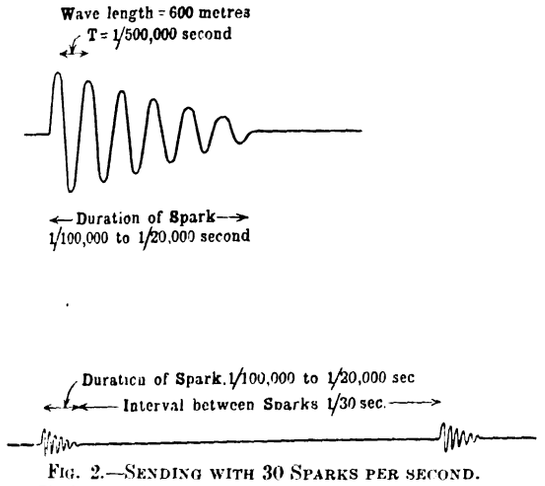

FIG. 2.—SENDING WITH 30 SPARKS PER SECOND.
The duration of a Morse dot is about one-twentieth of a second.

If the coil L_2, which with the aerial constitutes an oscillatory circuit of the same frequency as the circuit GKL_1, is loosely coupled with the coil L_1 so that about 5 per cent. of the magnetic flux of L_1 links L_2, a part of the oscillating energy will be transferred to the aerial and there partly radiated out into space and partly dissipated in the aerial, coil, and earth connection. The oscillogram (Fig. 3) shows the nature of the primary and aerial currents accompanying each spark. Owing to the loose coupling between L_1 and L_2 the transference of energy is very slow and the major portion is still dissipated in the spark-gap. From experiments made at the City and Guilds College it has been found that under the most favourable circumstances 30 per cent. of the primary energy can be transferred to the aerial. If the transfer of primary energy to the aerial is hastened by increasing the mutual inductance between L_1 and L_2, the energy surges backwards and forwards between the two circuits and gives us the phenomenon of beats. The oscillograms (Figs. 4 and 5) show the nature of the primary and aerial currents as the coupling is increased. Instead of a wave of one definite length, say 600 metres, a pulsating oscillation is sent out, which may be looked upon as made up of two ordinary damped waves with lengths of, say, 500 and 700 metres. This will be received almost equally well on the receiving aerial whether it be tuned to 400, 600 or 800 metres or any other intermediate wave-length.

In Figs. 9 and 10 are plotted the currents in the receiving apparatus as its natural frequency is varied. The two figures refer to different installations; in each case a series of curves is given for different degrees of coupling between the coils L_1 and L_2. With the ordinary spark-gap it is obviously impossible to increase the coupling much above 7 or 8 per cent. without sacrificing sharpness of tuning and thus causing undue interference with stations working at other wave-lengths. Apart from the question of interference, there is little increase of efficiency to be obtained by increasing the coupling beyond this value.

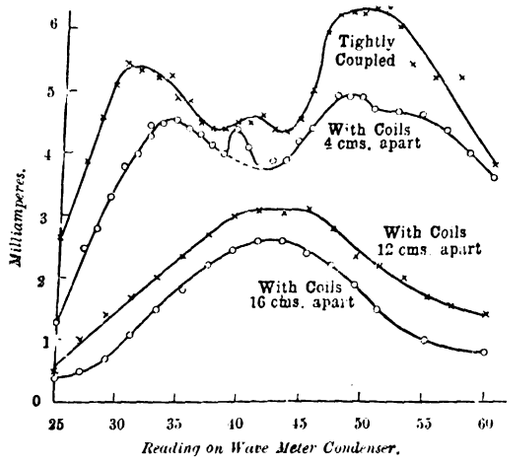

FIG 9.—SENDING ON FIVE-WIRE AERIAL, USING SMALL SPARK COIL AND PLAIN GAP WITHOUT AIR BLAST.

These are the conditions under which the majority of stations are working at the present time, but during the last three or four years a great amount of research work has been done with the object of improving these conditions.

In Fig. 10 it will be noticed that when the coupling is tight, the aerial oscillation contains waves of three different frequencies, one high and one low, corresponding to the constituents of the beats, and one of the natural frequency of the aerial alone. This shows that during a part of the time the aerial oscillated freely, uncoupled from the primary circuit. The reason for this can be seen from the oscillogram, Fig. 6. In the experiment to which Fig. 10 refers, the spark-gap was exposed to an air-blast, so that whenever the amplitude of the current in the primary oscillating circuit was small, there was a tendency for the air-blast to remove the column of hot air and metallic vapour and thus to extinguish the spark. This will obviously occur at a moment when all the energy is oscillating in the aerial and will prevent it surging back into the primary circuit. The aerial will now continue to oscillate at its natural frequency until the energy is all radiated or dissipated. In Fig. 10 not only was there an air-blast

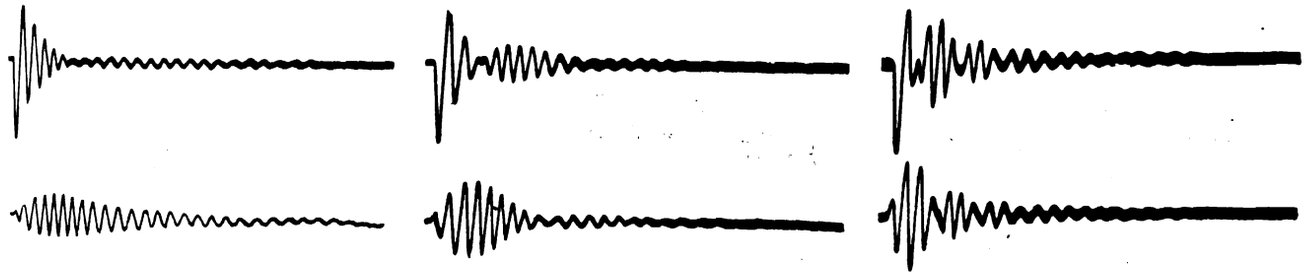

FIG. 3.

FIG. 4.

FIG. 5.

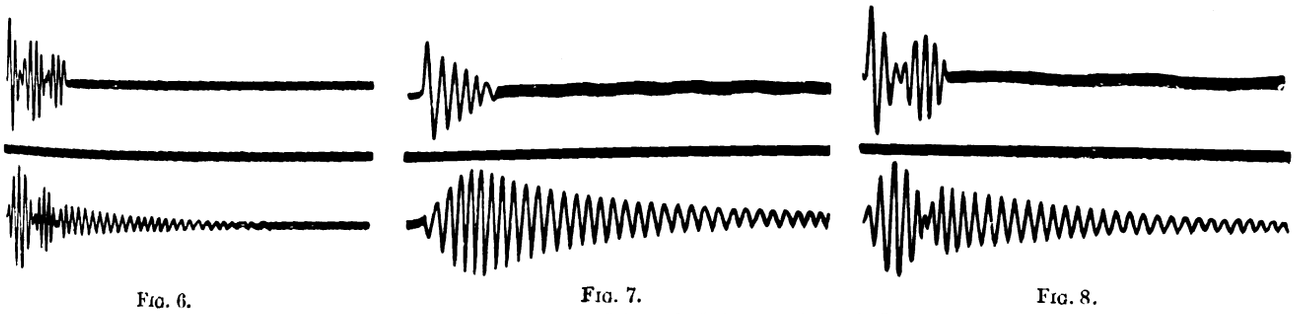

FIG. 6.

FIG. 7.

FIG. 8.

In all the Oscillograms the Upper Curve refers to the Current in the Primary Oscillating Circuit and the Lower Curve to that in the Aerial.

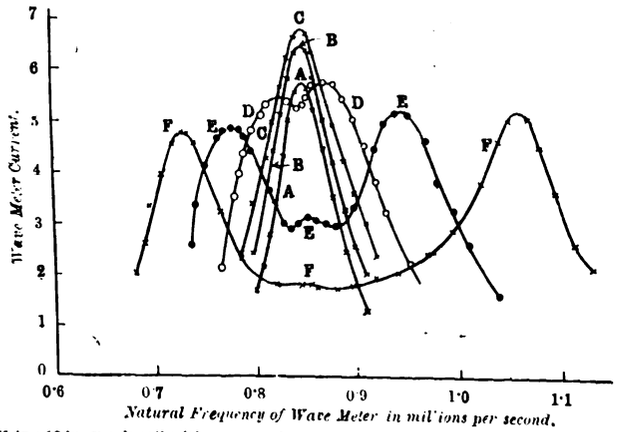
Digitized by Google

but the electrodes were comparatively large and the spark-gap short, so that no part of the spark was far removed from the large mass of cold metal tending to condense the metallic vapour and thus lower the conductivity of the spark.

This quenching of the spark was discovered in 1906 by Prof. Max Wien and was afterwards taken up by the Telefunken Company, who have evolved a form of spark-gap in which the quenching is very effective. With this gap the primary and aerial currents will be as shown in the oscillogram, Fig. 7. The gap acts as a very quick-acting minimum-current cut-out, and opens the primary oscillating circuit at the first opportunity, viz., when all the energy has been transferred to the aerial. The time during which the two circuits are coupled is very short, the energy wasted in the spark-gap is reduced, and the major portion of the energy oscillates freely in the aerial and is radiated as a damped train of waves at its natural frequency. In this way it is claimed that 75 per cent. of the output of the alternator is transferred to the aerial.

It is obviously advantageous to shorten the duration of the spark as much as possible by tightening the coupling between the coils L_1 and L_2, and thus hastening the transfer of energy to the aerial. If this be overdone, however, the gap will fail to quench at the first minimum and we may get the conditions shown in Fig. 8, or even Fig. 6, with a great loss both in efficiency and sharpness of tuning.

Wien first obtained quenching by the use of very short spark-gaps, and this is the method which the Telefunken Company has adopted, although other methods have since been discovered. The spark is made to occur between the parallel faces of discs of copper or silver placed about 1/100 in. apart, the discs being separated by thin annular rings of mica which also serve to shut the sparking spaces off from the air. The number of these discs in series depends on the voltage and power required. This form of gap is undoubtedly complicated and expensive, not only in first cost but also in subsequent up-keep.



Using 10 in. spark coil with mercury break. Length of spark gap 1·2 mm. with air-blast.
Primary capacity, 0·00567 microfarad. Secondary capacity, 0·00198 microfarad.
Resistance in secondary, 6·36 ohms.

A coupling = 2·9 per cent.	C coupling = 7·8 per cent.	E coupling = 21·4 per cent.
B " = 4·75 "	D " = 12·55 "	F " = 36·3 "

FIG 10.

Those who have picked up the time signals and weather reports sent out daily from Norddeich near Bremerhaven will have noticed that although the signals are very clear and easily distinguished from extraneous sounds, they often decrease in loudness after working for some time, and have been known to fail altogether for a few seconds in spite of the efforts of the operator. This may have been due, of course, to some exceptional cause not connected with the gap, but it is almost what one would expect when using such minute gaps as 1/100 of an inch. It seems therefore, at present, that the increased efficiency due to the quenched spark is obtained by the sacrifice, to a certain extent, of reliability and simplicity.

Turning now to the receiving apparatus, we find that the filings coherer has practically disappeared. The reception of the signals is now always aural. The detectors now employed in conjunction with a telephone receiver are not only much more sensitive than the filings coherer operating a Morse inker, but enable the operator to discriminate between the signals being sent to him and the various disturbances picked up by the aerial, which, as we have already seen, is a matter of ever-increasing importance.

The magnetic detector used by the Marconi Company is ideal in its simplicity and reliability, but is not so sensitive as the electrolytic or the mineral contact detector. The Telefunken Company have recently given up the electrolytic detector in favour of a detector of the latter type. Another type of detector used to a certain extent is the Fleming valve, which combines extreme sensitiveness with comparative simplicity and reliability.

Although there are many ways of arranging the receiver connections, Fig. 11 may be taken as typical of the usual arrangements when using a mineral contact detector. The high-frequency oscillation picked up by the aerial is transferred by means of the oscillation transformer L_3 L_4 to the tuned oscillatory circuit KL_4. Shunted across the condenser is the detector—consisting simply of a piece of zincite in contact with a piece of pyrites—together with the telephone receiver of several thousand ohms resistance. The telephone is shunted with a condenser, which must have such a capacity that it acts as a conductor to the high-frequency oscillations enabling them to pass through the detector without passing through the highly inductive telephone receiver, but as an insulator to currents of telephonic frequency, thus forcing them to pass through the telephone.

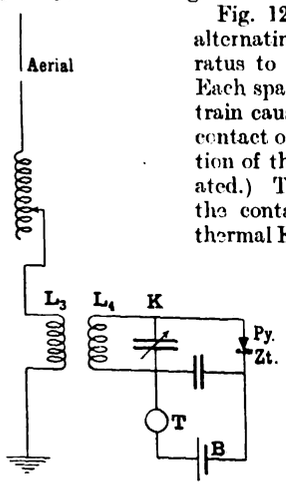


FIG. 11.

Fig. 12 explains the various stages from the alternating-current supply of the sending apparatus to the currents in the telephone receiver. Each spark causes a wave-train, and each wave-train causes a momentary heating of the point of contact of the detector. (In the figure the duration of the wave-train has been greatly exaggerated.) This will cause a momentary variation in the contact resistance and will also produce a thermal E.M.F., with the result that a momentary current passes through the telephone or, if, as is sometimes found advantageous, a steady current is maintained through the telephone by means of the cell B, this steady current will suffer a momentary variation.

Thus each spark gives an impulse to the telephone diaphragm and the pitch and nature of the note heard in the telephone receiver will depend entirely on the frequency and regularity of the sparks. It is here that one of the greatest improvements has taken place. Until recently the sparks followed one another so slowly or so irregularly that the sound heard in the telephone could not be called a note but was merely a crackling noise. A great number of stations are still working in this way, and the signals they send out are very difficult to distinguish from atmospheric disturbances and other extraneous noises. It is now realised, however, that by giving the signals a pure musical note of high pitch, they can be readily heard and distinguished above comparatively loud atmospheric disturbances and in spite of interference from other stations, unless these stations happen to be working with a note of the same pitch.

Another very important point in this connection is the great increase in the sensitiveness of the telephone receiver as the pitch of the note is increased.

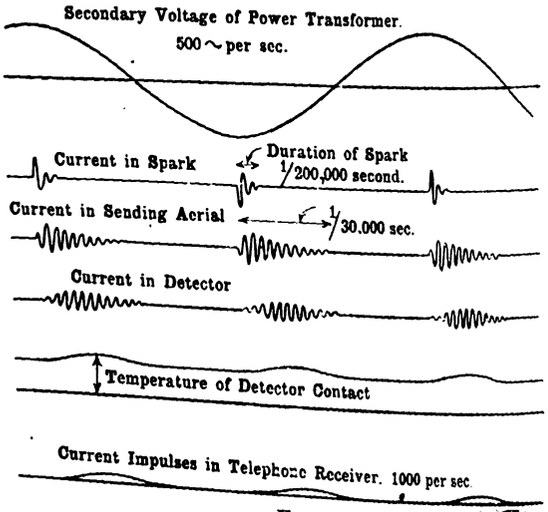

FIG. 12.

Wave length = 600 metres. A.C. supply from 500 ~ alternator.

To produce a musical note of high pitch it is necessary to make the sparks follow one another rapidly and with regularity. When sending at a speed of 20 words per minute the dot will be about 1/20 of a second, so that with a frequency of 30 per second the dot will consist of one, or at most a few sparks, whereas with a spark frequency of 1,000 per second, the dot will consist of 50 sparks. The former was quite enough to actuate a filings coherer, but would merely cause a blow on the telephone diaphragm, whereas the latter would give a short piping note in the receiver.

By increasing the alternating supply voltage or by shortening the spark-gap, a large number of sparks can be made to occur during each

Digitized by Google

half-cycle, but they will occur too irregularly to produce a musical note unless steps are taken to make the sparks occur at regular intervals. This can be done by replacing the stationary gap by two discs revolving at high speed, the rims of the discs being provided with projecting knobs between which the sparks jump.

The simplest way of obtaining 1,000 sparks per second with great regularity is to use an alternator giving 500 cycles per second and to adjust the voltage until the gap breaks down once every half-cycle as shown in Fig. 12. To ensure regularity the gap must be kept cool and the after-effects of each spark quickly removed. With the ordinary stationary gap this can be done by means of an air-blast, but with the Marconi revolving discs the air-blast will hardly be necessary. In the new Telefunken gap the quenching action, which we have already considered, has to extinguish the spark 1/200,000 second after it has jumped, so that after 1/1,000 second the gap should have lost all traces of the spark. The quenching action has thus to play a double part, the first affecting the nature of each spark and the resultant oscillation, and the second affecting the regular succession of sparks.

One of the most recent developments, although hardly yet beyond the experimental stage, is the introduction of the telephone relay. By placing one of the telephone relays, recently invented by Mr. S. G. Brown, between the detector and the telephone receiver, signals which are otherwise quite inaudible can be easily read. The Telefunken Company has recently experimented with an apparatus somewhat similar in principle and known as a tone augmenter.

The distances over which communication can be maintained with a given supply of power depends on the height and size of the aerial, on the nature of the intervening country and on the type of detector employed.

A safe guarantee under very unfavourable conditions is about 50 miles per kilowatt of alternator output but with favourable conditions and sensitive apparatus, distances of over 500 miles per kilowatt have been covered.

Practically all the radio-telegraphic apparatus working commercially or being installed at the present time is based on the principles which we have considered. With the exception of the spark-gap and the detector employed, the differences are non-essential. No mention has been made of the generation of undamped waves by means of arcs, as this system has not yet made the revolutionary changes in radio-telegraphy which many anticipated.

A NEW TREATMENT FOR PREVENTING SCALE IN BOILERS.*

BY T. R. DUGGAN.

It is not quite known why, in the generation of steam, certain salts of calcium and magnesium form hard crusts or scale. All engineers try to minimise this evil, knowing that $\frac{1}{8}$ in. thickness of scale means a loss of about 20 per cent., $\frac{1}{4}$ in. equals a loss of 40 per cent., and $\frac{3}{8}$ in. of scale a loss of about 50 per cent. of heat.

After many trials, Brandes has discovered an apparatus—"The Luminator"—which so changes water allowed to flow over it that when used in steam boilers little scale is deposited, old scale is softened and detached from the plates, and the precipitable salts are deposited as powder. I should hesitate to offer this for serious consideration were there not men of repute and integrity who have proved it in practice, as well as several plants working successfully in this country.

The treatment consists in allowing water to run down an aluminium plate of special dimensions, with corrugations of a particular size, according to the character of the water to be treated. It is only necessary to brush the channels well to keep them clean.

Storage tanks and mains, if far from the boiler, must be coated with a non-conducting composition—any bituminous varnish will do—and the water must reach the boiler as soon after treatment as possible. In any case, to get the maximum effect, the water must be used within seven days of its treatment.

The theory of the action of the "Luminator" is that, by the passage of water over the metal channels at certain speeds a current of electricity is induced, the water being negative and plates positive, and a kind of ionisation of the salts takes place, which makes them fall out in an amorphous form; at the same time aluminium is by friction and electrical action abraded from the surface as colloidal aluminium, which after a time is changed in the water. The best results are obtained when the "Luminator" is facing either north or south and exposed to direct light; in the dark the apparatus almost ceases to work.

The action within a steam generator is somewhat obscure, but in all probability the colloidal aluminium acts as a series of nuclei or active centres for the evolution of carbon dioxide and the crystallisation of salts, while the aluminium particles also combine with the dissolved oxygen of the water, and so deoxidise it. As corrosion of boiler plates is supposed to be caused by the presence of free oxygen in the water, this action should diminish the corrosion of boilers; such is found in practice to be the case. For instance, a boiler which was usually red with ferric oxide at the steam and water line, a belt of about 12 in. wide became purple black like new plates after using water treated by this process. This action is not confined to the steam and water junction, but goes on all over the boiler until it becomes coated with a smooth adherent semi-metallic coating of magnetic oxide of iron, which seems to prevent centres of crystallisation upon the plates and precipitates the salts as a powder.

* Abstract, from the "Journal" of the Society of Chemical Industry, of Paper read at the Chemists' Club, New York.

DISCUSSION.

Mr. W. A. CONVERSE said that it seemed to be generally agreed that the change effected by the "Luminator" was physical and not chemical. The water, before and after treatment, showed no difference upon analysis, but, upon boiling, was said to show considerable difference in precipitation. He had himself examined samples before and after treatment and could not find any difference.

Mr. F. B. HERRESHOF said that an experiment was tried with a feed water heater made in Boston some 15 or 20 years ago. It had a coil with a large surface exposed, so that the temperature of the feed was brought up to nearly 300° F. It was assumed that sulphate of lime would separate out at about 300° F., and it was claimed by the makers that all the carbonate would separate out. There were about 5 grains to the gallon of carbonate, as well as sulphate, and analysis showed that none of the carbonate was separated. Thus, at even that high temperature, the presence of carbonic acid which could not get away kept the calcium carbonate in solution; but calcium sulphate, if present in large enough amount, separated out. In a steam boiler the conditions were different, because the steam evolved swept away the carbonic acid as fast as it was disengaged from the bicarbonate; and the insoluble carbonate of lime, probably at first a fine powder, began to crystallise and form scale on parts of the boiler. Calcium sulphate was soluble in 400 parts of cold water; but at high temperatures, such as 300° F., it probably became dehydrated to a certain extent—at any rate it deposited on the tubes and parts of the boiler that became heated. The flues and crowns of boilers were hotter than the water, and it was there that calcium sulphate became attached as a very hard scale. How was this electric influence on a small scale to prevent calcium bicarbonate from decomposing at that temperature; or the carbonic acid from being swept out by the steam? How could it prevent calcium sulphate from decomposing when heated to a high temperature and forming scale?

Mr. JEROME ALEXANDER said that the fact that metals dissolved in water in the colloidal condition had long been known. In this particular case, aluminium and its compounds, whatever they might be, acted substantially as protective colloids. The various reactions described by Mr. Herreshof actually did occur; but in the presence of the aluminium or alumina compounds, the insoluble products separated as colloids and remained in suspension so that they passed out of the boiler when the boiler was blown off. He had never heard of a metal acting as a protective colloid, and he doubted if the metal aluminium could so act. Possibly aluminium oxide might, and so prevent precipitation. There appeared to be no doubt as to the facts stated by Mr. Duggan, and therefore one could only search for the most reasonable explanation of them. It looked as if the aluminium compounds, of whatever nature they might be, did act as protective colloidal substances.

Dr. FERRIS said that it was a common practice in the west to put zinc slugs in boilers, particularly tubular ones, where the heat was principally in the flues, to prevent the formation of scale. The precipitate remained in powder form and could be blown out very easily. But the zinc slugs in time dissolved. In an 80 H.P. boiler two or three zinc slugs of 25 lb. each would disappear in a month.

Mr. T. R. DUGGAN, in reply, said that a litre of water was run through the "Luminator" apparatus 10 times, and another litre of the same water was run over an enamelled plate the same number of times. Both samples were then heated to 80° C. for 10 or 15 minutes. The experiment showed a loss of 20 per cent. of temporary hardness in the water run through the "Luminator," while the other lost about 3 per cent. Aeration had nothing to do with it. There was no limit to the hardness which could be treated in the apparatus, but for such hard waters as reached, say, 80 grains per gallon on Clark's scale, an apparatus some 20 ft. long would be needed. The loss in weight of the aluminium was impossible to measure, it was so infinitesimal. A boiler using the "Luminator" should be blown off frequently, more especially in the first stages of its use, because old scale came off so rapidly that it accumulated at the bottom, and if permitted to remain there might result in burning the boiler. It was extraordinary what an effect the treatment had upon foaming. In every case where these machines had been used, foaming practically ceased. Waters containing ferrous sulphate could be treated, but ferrous carbonate would deposit on the aluminium plates, so they had to be continually cleaned, making it almost impossible to treat such waters. Milk, when passed through the apparatus, was found to keep an extraordinarily long time; whereas the same milk, not passed through it coagulated and became sour quickly. The corrugations had no function except to increase the surface of the plate. Zinc slugs were used in Great Britain many years ago, in marine boilers particularly, but for some unknown reason had been abandoned within the last 10 years.

The Rates for Subscription to "THE ELECTRICIAN" are as under:—

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" commence in April and October.

(This charge includes all the numerous Supplements.)

Vols. I to LXVI. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Jan. 31st in each year for the next following edition) 8s 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s; Europe, 2s; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents of the 1911 Edition sent free on application.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Reduction on quantity.*

LIVINGSTONE'S DIAGRAM FOR THE EASY CALCULATION OF SHAFT AND BEAM DEFLECTIONS. By R. Livingstone. 2s. 6d. nett. By post in tube, 2s. 10d.

"THE ELECTRICIAN" PRIMERS (8 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three Separate Vols.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free, abroad 13s.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A Fleming. Vol. I., 12s. 6d. nett. Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. [Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fifty-third issue of the Supplement published (Gratis) with the number of "THE ELECTRICIAN" for September 23, 1910, was the last of the monthly issues. "THE COMMERCIAL AND INDUSTRIAL SUPPLEMENT" to "THE ELECTRICIAN" is now issued weekly (Gratis). It will be found towards the end of the present issue.

NOW READY.

Vol. LXVI. of "THE ELECTRICIAN." Bound in Publisher's covers. Price 17s. 6d. Postage U.K. 1s. extra, abroad 2s. 6d.

Cases for binding Vol. LXVI. are now ready, price 2s.: post free, 2s. 3d.

SIR WILLIAM RAMSAY'S ADDRESS TO THE BRITISH ASSOCIATION.

Of all the tasks that fall to the lot of a distinguished man of letters or science, that of composing a Presidential Address to the British Association is by no means the least difficult. At the best he can please only a small percentage of his hearers, for some will understand and disagree, while many will not understand and will be correspondingly discontented. Sir WILLIAM RAMSAY, on the present occasion, has committed himself to nothing very deeply, but has touched on a variety of subjects calculated to interest that section of the general public which attends the British Association. Some of his points are, however, worthy of careful consideration, and not the least of these is to be found under the head of education: we refer to the evil of the present-day examination system. Unfortunately, it must be admitted that examinations of some kind are a necessity; there is at present nothing that could fill the gap which would remain if examinations were abolished. Bad as the system is, however, it is, nevertheless, susceptible of easy improvement. The trouble is that examiners, and even teachers, attach too much importance to examinations, and very often the tests themselves are conducted by the wrong persons. Perhaps the most glaring example of how not to do it is found in what is called the "external examination." A syllabus is laid down by an examining body, and students are carefully crammed in the subject-matter thereof for several months on end. At the conclusion of this period there is a final furbishing up with a text book at the very threshold of the examination room; then a paper of per-

Digitized by Google

haps ten questions, set with a view to ascertaining not how much a student has digested, but whether he has retained certain particular points. It is no exaggeration to say that a student who has been well taught may stand less chance of success in such a test than one who has been crammed on the bare syllabus. It must be evident that a teacher, who has had a student working under him for two or three years, knows far more about his man than the most distinguished examiner can find out in a couple of hours; yet the latter is the one to decide the fate of the unfortunate student. If Sir WILLIAM RAMSAY will only take some steps towards abolishing this iniquitous system we feel sure he will not lack support. That the importance of the matter is being realised will be apparent from the discussion which took place in Section L on Friday, when it was suggested that application should be made for the appointment of a Royal Commission to consider it.

The next point of interest in the Address relates to the positions of radium and its descendants in the periodic table, in which it is suggested that allotropy may be due to gain or loss of electrons, accompanied by positive or negative heat change. Taking as his text the disintegration of radium, Sir WILLIAM proceeds to descant upon the waste of coal which goes on. He calls attention to the enormous amount of energy contained in a minute quantity of radium, and illustrates it by striking figures. Unfortunately, however, the rate of liberation is far too slow to be of practical use, and, even if some means of accelerating it were discovered, then the quantity of radium available is much too small to have any effect on the rate at which our remaining coal store is being used up. Sir WILLIAM refers to the idea of obtaining energy from the tides, from the wind and from the sun, and, although this could be done, yet the amount would be insignificant, and, what is equally important, it would not pay—at all events, at present. Hence, until the happy day comes when some new store of energy is discovered, the best thing the nation can do is to take care of the coal it has left. It is calculated that England has enough coal remaining to last her 175 years; unless, therefore, some substitute is found the prospect is not a very cheerful one, for the nation can no more live without coal than a man can live without food. The right note is struck when Sir WILLIAM RAMSAY advocates the adoption of economical methods in the use of coal. Since the store must be exhausted, let it be exhausted as slowly as possible; if a method can be found of doing as much with a ton of coal as was formerly done with a ton and a quarter, let that method be adopted without delay. As a matter of fact, this is exactly what has been going on for a great many years, and the "*laissez-faire* plan of leaving to self-interested competition the combating of waste" is not so "*laissez-faire*" as the President might think. Strenuous endeavours are being made by engineers all over the country to reduce coal consumption, not perhaps from a purely altruistic motive, but because it pays. His suggestion that electricity should be generated at the pit's mouth and distributed at high pressure is a somewhat belated one; it has already been done, and in all probability the method will be extended as time goes on. It must be recognised, however, that a point is soon reached when this plan no longer becomes commercially possible. Presumably, this is the point at which Sir WILLIAM suggests State aid in the form of "loans at an easy rate of interest." We fear it will be a long time before any Chancellor of the Exchequer is bold enough to attempt the inclusion in his Finance Bill of a clause to transfer a portion of the national revenue to an electricity supply undertaking with the object of securing coal to posterity. It is a magnificent idea, but we fear it is a long, long way off realisation.

Sad as it may be, it seems that the saving of coal must, for very many years, be left to the efforts of engineers, who will use their wits, not in the interests of humanity, but with a view to diminishing that magical item "coal costs." Of course, if the State took over the electric supply industry, the matter would be on an entirely different footing; but we imagine that this also is not likely to take place in the immediate future.

Sir WILLIAM RAMSAY has done the country a real service in re-calling attention to this subject, and we can only hope that his Address will be read with the attention it deserves. At all events, his warning is a timely one, and he has discharged his duty by stating the case in such a way that there can be no mistake about it.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

The Elements of Telephony. By ARTHUR CROTCH. (London, 1910: E. & F. N. Spon.) Pp. 90. 1s. 6d. net.

Within the limits of a modest volume of 90 pages the author has outlined the main features of a present-day telephone system in a way which should enable a reader who has some little knowledge to start with to obtain a clear and intelligent understanding of the inner workings of a modern exchange.

The general arrangement of the book is excellent. After a discussion of first principles in the introductory chapter, the reader is led by easy stages from the simple magnetic telephone of Bell up to the intricacies of the large common battery exchange. The text is plentifully illustrated by circuit diagrams and photographs of apparatus. The former, although of necessity rather small, are nevertheless very clear and show evidence of considerable care having been taken in their selection and preparation.

In a book of this kind one does not look for detailed descriptions of the thousand-and-one types of apparatus now in use, but rather for an explanation of the salient features of a few of the more important ones, with a view to bringing out the underlying principles upon which their action depends and the conditions they are designed to meet. In this respect the author is particularly successful and his book can be recommended as eminently suitable to place in the hands of the elementary student to form a foundation for the more detailed knowledge he will afterwards acquire. H. S. T.

William Thomson, Lord Kelvin—His Way of Teaching Natural Philosophy. By D. WILSON. (Glasgow, 1910: J. Smith & Son.) Pp. 56. 2s. nett, cloth; 1s. nett, paper.

In this book the author gives his recollections of certain scenes in the natural philosophy class at Glasgow University in the early eighties, and his own personal ideas about Lord Kelvin's method of teaching. The images presented seem to us very distorted, the author and his friends forming a very conspicuous group in the centre. They seem to have belonged

Digitized by Google

to that class of student which is always on the look-out to "show off," not infrequently with disastrous results. The first chapter, on the "metric system," purports to portray a scene in the class-room and illustrates the difficulties of teaching "raw material" in bulk. In the next chapter several happy prophecies made by Kelvin in 1884 are given. They illustrate how clearly he saw the lines on which progress in electric lighting and traction would be made. The author does not throw much light as to what Kelvin meant by the "vital principle," but he airs his knowledge of Oriental religions, and thinks that Kelvin must have been actuated by the *Golden Rules*.

In the last chapter the author describes how, in a degree examination on natural philosophy, he answered the last question in a way which, although correct, was more fitted for the pages of "Punch" than for examiners' reading. The examiners being Scotch, and consequently being able to appreciate a joke without loss of dignity, decided that justice would be satisfied if the culprit had a personal interview with Sir William. The interview shows Sir William in a very pleasant light, but we are doubtful, notwithstanding the statement to the contrary, whether he really succeeded in making the author see the principle of the conservation of energy. "Conservation of energy was seen to be a verbal symbol of one aspect of what Carlyle called the 'fact of facts,' the living universe, whose 'energy' includes, as an insignificant item, the whole human race from the beginning of time, and can no more be measured by us than the ocean can be bottled in our laboratories." Personally, the reviewer thought that the conservation of energy was something quite different, but still, if philosophers are willing to accept it in the form set forth by Mr. Wilson it seems a pity to try and upset their faith.

Elektrische Winke für Architekten und Hausbesitzer By Dr. L. Block and R. Zandy. (Berlin, 1911; Julius Springer.) Pp. iv. + 151. M.2.80.

Messrs. Block and Zandy have written a very interesting little work on electric installations generally which undoubtedly fulfils the title they have given it, as it certainly does contain a large number of useful wrinkles which should appeal not only to architects and householders for whom it has been mainly written but also to electric-lighting engineers in general. Of course, there are many points of difference between English and Continental installation practice which must be considered in using the book. Although, as pointed out by the authors in their introduction, the architect with a knowledge of electrical installation practice and requirements has it in his power by making from the start suitable provision for the cable runs, &c., of cheapening and facilitating the arrangement and installation of electrical wires in new buildings—of special importance in the case of buildings with ferro-concrete walls and floors—this should be done by the architect under the guidance of a responsible electrical engineer, not by the architect alone. It is impossible for the architect to gain all the necessary knowledge and experience, however well the facts are put together and condensed, in a single volume. The electrical engineer is either not consulted at all in far too many cases or is called in too late.

Chapter I. contains remarks on the installation generally—position of the connections to the supply, main runs, rising mains, distributing centres, &c. It also points out the advisability of making the necessary provision for fixing and running the wires in the case of concrete floors and gives methods of carrying this out. Chapter II. is on electric illumination. It deals with all the various types of incandescent and arc lamps in a brief but satisfactory manner. The candle-power and watt consumption are given in a very clear tabular form, especially those for arc lamps. The paragraphs on the selection of lamps, the number and candle-power, are very good, and the table for calculating the number of lamps required for different classes of rooms will also be found very instructive; it is, of course, in Hefner candle-power per square metre. The illustrations in this chapter of examples of interior illumination, both direct and indirect, are also very good. Staircase and shop-window illumination are, further, separately considered.

Chapter III. is on electric cooking and heating. Many useful data will be found in it as regards the watt consumption of various cooking utensils. Electric power in dwellings is explained in Chapter IV. It includes information and illustrations of lifts (push-button system), ventilating fans, vacuum cleaners, water pumps, small charging outfits for charging batteries for electric automobiles, electrically-driven refrigerators, &c. Chapter V. sets forth the advantages of electrically driven contractors' plant and gives excellent illustrations showing how electric power can be utilised by the contractor in building operations in numberless ways to expedite the work of excavating, removal of rubbish, &c., elevating, and so on.

The book is well and clearly written and well illustrated, and contains a number of useful hints; it reflects considerable credit upon the authors who have succeeded in setting forth the advantages of electric lighting and power in a simple and decisive manner.

STUDIES IN LIGHT PRODUCTION.*

BY R. A. HOUSTOUN, M.A., PH.D., D.SC.

(Lecturer in Physical Optics in the University of Glasgow.)

Summary.—In these studies the author deals with the theory of light production, the scope being briefly indicated by the following contents: (1) The distribution of the energy in the spectrum and the measuring of efficiency. (2) The importance of "black body" radiation and the experimental realisation of the black body. Comparison of the energy curves of a black body and of platinum, and the variation of the position of maximum energy with temperature. (3) Mechanism of flame, and the temperature, energy and efficiency of flames. (4) The Welsbach mantle and selective radiation. (5) Radiation and efficiency of the carbon glow lamp. (6) Physical properties and temperature of the arc. (7) Temperature and energy curves of the Nernst glower. (8) Efficiency of the metal filament. (9) The mercury arc and its difficulties. (10) The light of the future and the possibility of obtaining "cold light."

No. 1.—The Energy Spectrum.

It is a commonplace that our means of producing artificial light are all very inefficient. What the efficiency is in each case and the circumstances on which it depends are not generally known. The information lies scattered in a number of different periodicals. In these studies the most important facts have been collected and arranged both for the sake of reference and for information as to the lines future progress is most likely to take.

Light waves carry energy with them. Every source of light is radiating energy, and this energy is being absorbed and converted into heat by the objects on which the rays strike.

If a ray of white light fall upon a prism a spectrum is produced. Part of the energy of the original ray is reflected at the surfaces of the prism, part is absorbed in the prism and the rest is spread over the different colours of the spectrum. Suppose that the spectrum is received on a screen and we fix our attention upon that portion of it bounded by the wave-lengths λ and $\lambda + d\lambda$. The rays, the wave-lengths of which lie between λ and $\lambda + d\lambda$, bring every second a certain amount of energy to the screen; let this amount of energy be denoted by $E_\lambda d\lambda$. E_λ is a function of λ. The total energy arriving per second on the screen is $\int E_\lambda d\lambda$, the integration being carried out over the whole spectrum.

This function E_λ is very important in the theory of the efficiency of light sources, and it is necessary to consider how the variation of E_λ with λ can be determined experimentally. The brightness of the different parts of the spectrum as estimated by the eye is of no use, for the sensitiveness of the eye to different colours is by no means the same. The light energy of the different colours must be turned into heat and the quantity of heat measured. Four different instruments may be used for this purpose—the thermopile, the bolometer, the radiometer and the radiomicrometer. These instruments and the methods of working with them are fully described in

Kayser's "Spectroscopie," Vol. I., Chapters V. and VI., and in Baly's "Spectroscopy," Chapter VIII. There is also an extremely important article in the publications of the Bureau of Standards ("Instruments and Methods of Radiometry," W. W. Coblentz, Bull. Bureau of Standards, 4, p. 391, 1908) in which the relative advantages of the four methods are discussed both from the literature of the subject and as a result of tests made by the author. The radiometer has been used chiefly by E. L. Nichols and his pupils in America. It and the radiomicrometer possess the advantage that they do not require galvanometers and the disadvantage that they cannot be moved during the set of observations. Here I shall mention only a few points about the thermopile and radiomicrometer, of which instruments good types are on the market in this country. (Cambridge Scientific Instrument Co.; Keiser & Schmidt, Berlin-Charlottenburg.)

The Rubens linear thermopile is made of iron and constantan wire of diameter 0·1 mm. to 0·15 mm. It has a resistance of about 4 ohms. Constantan is an alloy consisting of 60 per cent. Cu and 40 per cent. Ni. There are 20 junctions arranged on a length of 2 cm. for receiving the light, and, of course, another 20 unexposed junctions. The junctions are soldered with beads of silver, which are flattened into discs of about 1 mm. diameter, so as to present a large surface to the rays. For mapping energy curves the thermopile is mounted in the telescope of a spectroscope, just behind the focal plane of the latter, and there are shutters in that plane for regulating the width of spectrum that is to be admitted to the thermopile. Wires lead from the thermopile to the galvanometer. When plotting an energy curve—*i.e.*, determining the function E_λ—the source of light is focussed on the slit and a screen placed before the latter. The screen is then removed and the galvanometer deflection noted. The operation is then repeated for other points in the spectrum. The galvanometer deflections do not give E_λ directly; the "slit width" correction must first of all be made. Owing to the fact that the dispersion of the prism is not normal, the range of wave-lengths falling on the thermopile at different points in the spectrum—*i.e.*, $d\lambda$—is not always the same. As the deflections are proportional to $E_\lambda d\lambda$, in order to obtain the variation of E_λ we must allow for the variation of $d\lambda$. To do this we draw the calibration curve of the spectroscope—that is, plot s, the telescope reading in angular measure in terms of λ. If we then determine $\frac{ds}{d\lambda}$ and multiply the deflections by $\frac{ds}{d\lambda}$, the result will be proportional to E_λ.

Another correction must be made before the energy curve is obtained. The absorption of light in the instrument must be corrected for. Glass absorbs all wave-lengths greater than 3μ; but if a glass prism and glass lenses be used, the deflections are influenced by the absorption of the glass from 2μ on. An energy curve cannot be plotted beyond 3μ with a glass prism and lenses, and if the region $2\mu-3\mu$ is to be determined, the absorption of the glass must be allowed for. Quartz transmits much further into the infra-red and ultra-violet than glass does; but for the infra-red region rock salt and fluorite are the most suitable materials for the prism and lenses. The absorption of the aqueous vapour and carbon dioxide in the atmosphere must be allowed for; at certain wave-lengths it influences the deflections appreciably. It is better to use mirrors in the spectroscope than lenses; all metals reflect infra-red rays well, and the focal length of a mirror being independent of the wave-length, there is no trouble in focussing the thermo-pile.

In the radiomicrometer we have both thermopile and galvanometer combined. It consists of a single loop of wire with a thermo-junction at one end suspended between the poles of a magnet by a quartz fibre. In comparison with the thermopile it has a very steady zero, but its sensitiveness is distinctly less than that of the latter when connected with a low resistance Du Bois Rubens galvanometer, which has a resistance of 10 ohms and a sensitiveness of 3×10^{-10} amperes/$\frac{1}{2}$ mm. at metre distance for a period of 5 seconds. As the radiomicrometer cannot be moved, the spectroscope telescope used with it must remain fixed.

Of course, it is only the strongest sources of light, of which the energy curves can be determined directly with a thermopile or similar instrument. The light radiation from the brightest sodium flame produced by a bunsen burner would not produce a readable deflection. If the energy curve of a weak source is required, the latter must be compared with a strong source by a spectrophotometer in the visible spectrum, and by a photographic method in the ultra-violet, and the energy curve may thus be determined indirectly. There is no means of determining it in the infra-red.

The most satisfactory way of determining the wave-length in the infra-red is to calculate it from the index of refraction of the quartz or fluorite prism, or to place a very thin film of water before the slit and use its absorption bands as reference points. The positions of the latter have been accurately determined. The methods described in the text books—auxiliary gratings and interference bands—are expensive, or much more troublesome.

Suppose, now, that a number proportional to E_λ is plotted as a function of λ from end to end of the spectrum. If we wish to find what proportion of the total energy radiated is light, what we have to do is to erect ordinates at $0{\cdot}410\mu$ and $0{\cdot}760\mu$, the commonly accepted ends of the visible spectrum, and find the ratio of the area included between these ordinates to the area of the whole curve. E. L. Nichols has named this ratio the radiant efficiency of the source. At the same time he has introduced another quantity, the luminous efficiency of the light source. This is defined to be the ratio of the total energy radiated per second as light to the total energy consumed per second by the source.

Let Q = total electrical energy consumed per second, R the total energy radiated per second and L the total luminous energy radiated per second; then

$$L/Q = \text{luminous efficiency}$$

and

$$L/R = \text{radiant efficiency}$$

of the lamp.

In the case of an electric glow lamp the total energy consumed per second can be easily found from the current and the difference of potential between the terminals of the lamp. In the case of a gas flame we require to know the total quantity of gas consumed per second and the amount of chemical energy liberated by the combustion of unit mass of gas. The luminous efficiency is always less than the radiant efficiency. If the energy not radiated were zero—that is, if there were no conduction and convection losses—they would have the same value. Both quantities are extremely useful in the discussion of the performance of a light source.

A glass cell 1 cm. thick filled with water stops all wave-lengths greater than $1{\cdot}4\mu$ entirely, and absorbs the infra-red between $1{\cdot}4\mu$ and the visible spectrum considerably, but does not absorb the visible spectrum appreciably. The energy in the ultra-violet of the common light sources is very small indeed, and may be neglected in comparison with the light energy. Hence, in order to separate the light from the dark heat, it used to be the practice to pass the rays through a water filter or through a solution of alum. But a water filter transmits much dark heat as well as light, and if we attempt to determine the radiant efficiency by taking the deflections of a thermopile with and without a water filter before it the value we obtain is much too high. Some experimenters have attempted to correct for the dark heat transmitted by the water by means of solutions of iodine in carbon disulphide, which were supposed to absorb all the light and nothing but the light. The utter untrustworthiness of this correction has, however, been demonstrated by E. L. Nichols and W. W. Coblentz. ("On Methods of Measuring Radiant Efficiencies," Phys. Rev., XVII., 1903, p. 267.) Even if we use the correction the values of the radiant efficiency are still too high. Aqueous solutions of ferrous ammonium sulphate have recently been suggested as a means of separating the light from the dark heat. But it has been shown (R. A. Houstoun and J. Logie, Phys. Zs., 11, p. 672) that though they are considerably better in this respect than water filters, yet they are not good enough to afford us a satisfactory method of determining the radiant

Digitized by Google

efficiency. It should be noted that, in spite of the widespread opinion to the contrary, alum solutions do not absorb dark heat any better than water does.

Almost all the accurate determinations of radiant efficiency yet made have been carried out by a method introduced by K. Angström, which will be described later. I have recently determined ("The Efficiency of Metallic Filament Lamps," Proc. Roy. Soc., Edin., Vol. XXX., p. 555, 1910) the radiant efficiency of some metallic filament lamps by a method which, to me at least, seems preferable. The radiation was first measured in the usual way by a thermopile and galvanometer with and without a 1 cm. thick water filter, and the fraction of the total radiation transmitted through the filter determined (F). The light was then focussed on the slit of a spectroscope through the same water filter and an energy curve taken. The deflections were plotted against the scale readings and an ordinate set up at 0·76μ. The area on the side of shorter wave-lengths divided by the whole area then gave the ratio (f) of light transmitted by the filter to the total radiation transmitted. It was then only necessary to find what fraction of the incident light was transmitted by the water cell. This was done with a spectrophotometer for four different points in the spectrum and the value found, 0·84, was the same for each point. The radiant efficiency was then F/0·84.

The determination of luminous efficiency is much more difficult. It was the luminous efficiency that was aimed at by the old calorimetric method of measuring the efficiency of a glow lamp. The lamp was placed in a glass calorimeter and then in a similar copper one, and from the rise of temperature in the two cases, with various corrections, the ratio of the energy radiated as light to the whole energy supplied could be calculated. The heat lost by convection and conduction went to raise the temperature in both cases. But the method is in principle bad; the whole energy and the dark heat are measured and the light is obtained as the difference of two much larger quantities, both subject to considerable error of observation. Also, as has been already mentioned, water does not absorb all the dark heat, and hence some escapes from the glass calorimeter. If we wish to determine the luminous efficiency we must first of all determine the radiant efficiency; we must then find the total rate at which energy is being consumed by the source, and we must finally determine the total energy radiated per second. The neatest way of finding the energy radiated per second in any one direction is by some such instrument as Angström's pyrheliometer. To find the total energy radiated per second it is necessary to find the energy radiated in different directions and to integrate over the sphere.

So far we have considered light solely from the objective standpoint. It is now necessary to consider it in relation to the eye. The same quantity of energy in different parts of the spectrum does not produce the same intensity of sensation in the eye. The well-known curve shown in Fig. 1, taken by Sir Wm. Abney, illustrates this. The brightness of the different colours of the spectrum of the crater of the arc was compared in turn with the brightness of a white light, which could be varied by a rotating sector. The ordinates of the curve are obtained in this way, and are proportional to the brightness or luminosity of the part of the spectrum in question as seen by a normal eye. If we took an energy curve of the arc crater with the same prism and lenses, plotted it on the same diagram and divided the ordinates of the energy curve by the ordinates of the luminosity curve, the quotient would be proportional to the quantity of energy necessary to produce the same luminosity at different points in the spectrum. It varies widely throughout the spectrum, having a minimum at 510 $\mu\mu$ for low intensities, and increasing rapidly on both sides of this minimum. At 410 $\mu\mu$ it has then a value roughly 50 times the minimum value, and at 610 $\mu\mu$ one roughly 40 times the minimum value. According to P. G. Nutting ("The Luminous Equivalent of Radiation," Bull. Bureau of Standards, 5, p. 273, 1908), who refers to the reciprocal of this quotient as the visibility of the colour, the quotient for low intensities has the form $e^{\kappa(\lambda-\lambda_m)^2}$ for the normal eye, λ_m being the wave-length of the minimum measured in 10^{-5} cm., and κ being equal to 4·5.

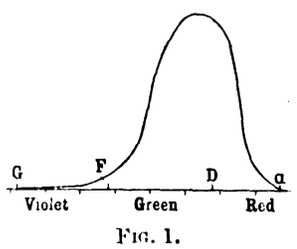

Fig. 1.

For higher intensities the maximum of visibility moves towards the yellow, and the visibility in the neighbourhood of the maximum does not vary so much with colour. At low intensities vision seems to be performed by the retinal rods alone, and at higher intensities mainly by the cones. The transition from rod to cone vision is very gradual; they are about equally in play at ordinary working intensities. It is the transition from rod to cone vision that displaces the maximum of visibility with increase of intensity.

As the brightness of the light produced depends not only on the energy of the radiation, but also on its colour, luminous efficiency, as we have defined it, has no direct connection with efficiency as ordinarily understood in connection with artificial illuminants. One source which radiates more energy between 410 $\mu\mu$ and 760 $\mu\mu$ than another may have that radiation distributed so disadvantageously over the spectrum that it gives less light than the other. C. E. Guillaume has, therefore, proposed to specify the efficiency by multiplying E_λ for every wave-length by the "visibility" for that wave-length, taking the maximum visibility in the spectrum as unity, and by dividing the quantity thus formed by the total power supplied. It may be urged against this proposal that the visibility of different colours is not very well known yet, and that in watts per candle or in candles per watt we have already a term that conveys Guillaume's meaning. Also the relative visibility of the different colours varies with their intensity. And the ordinary method of testing lamps on the photometric bench is certainly a much shorter and more accurate method for getting their watts per candle than the one suggested in Guillaume's definition. It seems to me, therefore, better to retain the old way of specifying luminous efficiency. It has, in addition, the merit of simplicity.

Various observers at different times have attempted to determine what has been called the mechanical equivalent of light—namely, how much energy is it necessary for a source to radiate per second in order to produce 1 c.p. of light. From the foregoing it is obvious that the mechanical equivalent of light must vary with the nature of the source. As a result of a recent determination, C. V. Drysdale "On Luminous Efficiency and the Mechanical Equivalent of Light," Proc. Roy. Soc. A, 80, 1907-08, p. 19), using glow lamps, obtained 16·7 candles per watt for yellow-green light.

The visibility is greatest for green light. This, consequently, is the cheapest kind of light; but, being monochromatic, it is of no use for the purpose of discriminating colour. The ideal illuminant must make all colours appear the same at night as by day. It might be possible to make a creditable white light by combining two monochromatic sources, but for making all colours appear the same by night as by day the illuminant must have all the colours of the spectrum in the same proportion as average sunlight. Consequently, we arrive at the specification of the energy curve of the perfect artificial illuminant after which technology is striving. *Throughout the visible spectrum it will have an energy curve like that of average sunlight; the energy curve will cease at the limits of the visible spectrum.*

(To be continued.)

Simmer Pan Power Station.—The June "Translations" of the South African Institute of Electrical Engineers, which have only recently come to hand, contain a brief description of this power station, the members of the Institute having paid an official visit to the station on July 15th last. The party was received by the chief engineer, Mr. Bernard Price, who is vice-president of the Institute.

THE BRITISH ASSOCIATION AT PORTSMOUTH.

(From Our Special Correspondent.)

Wednesday, August 30th.

The eighty-first meeting of the British Association commenced this evening at Portsmouth, when Sir William Ramsay, K.C.B., F.R.S., delivered his Presidential Address in the Town Hall. In requesting Sir William to take the chair, Prof. Bonney, the outgoing President, referred to his great work in radio-activity, and said that he might be said to have brought down helium from the sun to earth by showing that it was all the while lurking in various terrestrial substances.

Since the new President's address has already been published in The Electrician, there is no necessity to refer further to it here except to say that it was warmly received by an appreciative audience. The Mayor of Portsmouth moved a vote of thanks to Sir William Ramsay, and at the same time extended a hearty welcome to the British Association on the occasion of its first visit to Portsmouth. Prof. Dixon seconded the motion, which was carried with acclamation.

Thursday, August 31st.

Work commenced in real earnest this morning when the respective Presidents of Sections opened the proceedings by reading their addresses. Reference has been made already to Prof. H. H. Turner's address to Section A, and there is nothing of electrical interest in Prof. J. H. Biles's address to Section G.

After a vote of thanks to Prof. Biles had been proposed by Sir William Ramsay, seconded by Mr. Alexander Siemens, and carried unanimously, Mr. Worby Beaumont read his Paper on "The Origin and Production of Corrugation of Tramway Rails." The author contended, as will be seen by the Paper which we publish on another page, that the primary cause of corrugation is really a triple one: (*a*) The great weight of the cars, (*b*) the small diameter of the wheels employed, (*c*) the high speeds at which cars are run. These three factors together, he maintained, are such as to render it impossible to procure any material which will not be deformed under the stresses put upon it. As a result of experiments, conducted at the request of Mr. Fell, on certain London County Council equipment, he came to the conclusion that the pressure between wheel and rail, in the case of driving wheels, rose as high as 100 tons per square inch when the car was rounding curves, and in the case of pony wheels it was even 120 tons. Hence, it is evident that the pressure per unit area exceeds the limit of elastic compression of the material of the ordinary rail, and that flow or deformation would occur if it were not that the area pressed is supported by the surrounding material and held *encastree*, so that flow cannot occur. The result is detrusion of both edges of the rail, but, of course, the inner is ground down by the flange of the rail. Another result is that the material of the rail moves forward with the advancing wheel until it becomes so compressed and hardened that the wheel mounts it, making it harder still, and then begins to make another depression on the other side. A third result is the minute crumbling and pitting of the rolled surface. Mr. Beaumont put forward four suggestions for dealing with the difficulty. The first was to reduce the weight of the car; this would have the effect of reducing the pressure between the tyre and the rail. He did not observe, nor did any speaker in the discussion which ensued, that decreasing the weight of the car would have the effect of decreasing the area of contact, and, therefore, to some extent, defeating its own object, since pressure is equal to force divided by area. His second suggestion was that larger wheels should be used; this, of course, would increase the contact area and therefore reduce the pressure. Speed reduction was his third point, and the use of harder material for the rails his fourth. With regard to this latter, however, he admitted that harder rails would necessitate the employment of methods more costly than those now in use. Mr. Alexander Siemens opened the discussion, and said he could scarcely imagine that Mr. Beaumont believed his conclusions to be possible—viz., that the speed of cars should be reduced and the wheels made larger. He thought Mr. Beaumont was quite wrong to suggest harder rails; his own opinion was that they should be softer or, at all events, more elastic. This would secure a much larger area of contact by permitting the wheel to sink in as it were. Directly the wheel moved on the nature of the rail material would cause the depression to disappear. He suggested that rails should be made of hard material with a tread of soft or elastic material on the top. Sir William White said that corrugation was experienced on gun-beds due to the motion on recoil; this, however, had been overcome after lengthy experiments had been carried out, but he did not divulge the nature of the experiments. He did not agree with Mr. Siemens that the rails should be made of softer material. After one or two other speakers had interpolated remarks, Mr. Beaumont replied to the discussion. He asserted, with due respect to the President of the Institution of Civil Engineers, that Mr. Siemens had devoted very little study to the use of tramway materials if he could advocate the employment of soft rails, and in reply to a protest from Mr. Siemens he (Mr. Beaumont) said he thought Mr. Siemens meant ductility when he said elasticity. The question of speed reduction was a very difficult one, and would remain so owing to the fact that a tramcar was bound to keep to the rails. The consequence was that a high speed had to be attained whenever a clear course was available in order that the average speed could be kept up to the desired magnitude. He thought it would be quite possible to employ larger wheels, but at the same time he recognised that this would lead to a considerable modification in the design of cars. Corrugation was becoming a very serious matter, for it raised the cost of repairs and renewals to such a figure as to make some tramway systems financially impossible without aid from the rates. Moreover, the noise and vibration were becoming almost unbearable. He did not think it possible to do anything with the wheels or tyres so as to make the latter elastic, and thereby increase the area of contact with the rails.

The next Paper on the list was on the "Anschutz Gyro Compass," by Mr. G. K. B. Elphinstone. This device, as its name implies, is a gyroscope, carried on a float which rests in an annular vessel of mercury, the centre of mass of the whole arrangement being brought about 4 in. below the surface of support. Its action is entirely independent of the earth's magnetic field or of the presence of magnets or iron in the neighbourhood. The rotating element is electrically driven, and the air current set in motion by it is employed for damping purposes. The combined action of gravity and the earth's rotation is such as to cause the gyroscope always to point to the geographical north. Mr. Elphinstone showed a model compass, while in an adjoining room several instruments were exhibited. There was no discussion on the Paper, as time had slipped away, and it was one o'clock when the author finished.

In the afternoon a visit was paid to the Dockyard, and the visitors were shown over H.M.S. "St. Vincent." This visit was the occasion of a good deal of grumbling among members of the Association at the lack of organisation apparent. Association officials seemed to be conspicuous by their absence, and this may have accounted for the fact that very little of interest was seen. Our attention was directed to the wireless aerial, but we were informed that no one could be allowed to look inside the operator's cabin. Only by persistent efforts did a chosen few manage to get down to the engine room. This is divided into two distinct portions and it is necessary to go up to the main deck in order to get from one to the other. The ship is driven entirely by turbines of the Parsons type, the condensers being of the surface type. When running at full speed, the coal consumption works out at about 1·5 lb. per horse-power-hour, but when running at half speed the coal consumption goes up to about 3·5 lb. It appears that, by an Admiralty order, the turbines may not be opened up within five years from

Digitized by Google

their installation. The gun-laying is carried out by hydraulic power and ammunition hoists, &c., are similarly worked; electric motors are, however, employed for ventilating.

In the evening a reception was given by the Mayor and Mayoress on the South Parade Pier.

Friday, September 1st.

After a discussion on the principle of relativity, Section A divided into two portions, one of which proceeded to listen to Papers on Mathematics and the other on General Physics. The first Paper in the latter category was "On the Radiation producing Aurora Borealis" by Mr. L. Vegard. Starting from the view advocated by Birkeland that auroræ are caused by electric solar radiations, the author treated the problem of determining their physical properties. From the form and structure of the luminosity a method is found of examining the way in which the solar rays are absorbed by matter, and he arrived at the conclusion that the law of absorption of the solar rays is essentially the same as that of α-rays. This coincidence with regard to law of absorption led the author to draw further consequences of the hypothesis that certain auroral forms are caused by α-rays. The author finds that the α-ray hypothesis, as far as our present knowledge goes, explains in a satisfactory way the properties of the definite auroral forms, while the assumption of a radiation of the β-ray type meets with serious difficulties.

The next Paper was entitled "A Friction Permeameter," by Mr. W. H. F. Murdoch. This we hope to publish in next week's issue of THE ELECTRICIAN.

Section G opened with a Paper on "Electrical Drives for Screw Propellers," by Mr. H. A. Mavor; the Paper is dealt with elsewhere in this issue. The author advocated the employment of three-phase working, and gave details of several installations in actual operation. It seems that high-speed propellers give very poor results on low-speed vessels, and hence a difficulty arises if it is desired to employ economical high-speed engines. In the case of turbines the problem resolves itself into a choice between mechanical gearing and what may be regarded as electrical gearing. Mr. Mavor described systems in which engines were employed for driving three-phase generators, the motors being connected directly to the propeller shafts. By this means very large speed reductions could be obtained with a trifling loss of power. Opening the discussion, Prof. W. E. Dalby asked for efficiency figures at full and half loads. He also inquired whether there were not serious flywheel effects obtained by connecting a motor of some 12 ft. in diameter to the propeller. Prof. Petavel suggested that the high efficiency obtained might compensate for the losses in transmission. At the same time he could not help thinking that additional liability to breakdown was introduced by the presence of the dynamo, motor, &c., as well as the engine, which had to be there in any case. Dr. J. Morrow said he thought that the electric drive might be very suitable for low-speed ships, but he was not convinced that it could be applied with advantage to high-speed vessels. He also suggested that the U.S. Navy authorities were discarding turbines in favour of reciprocating engines, but Sir William White at once explained that only in in the case of one slow-speed vessel, now building, were they putting in a reciprocating engine, and, therefore, Dr. Morrow's statement was hardly accurate. The chairman, Prof. Biles, asked whether short-circuiting would take place if the motor were flooded, and if so what would happen. In his reply, Mr. Mavor said that the full load efficiency was about 96 per cent., but that, as a rule, he preferred to work with large air-gaps and amply proportioned machines, the result being that the efficiency worked out at about 90 per cent. Although he had had considerable experience with large motors directly connected to propellers he had detected no trouble due to flywheel action, as suggested by Prof. Dalby. He quite agreed that it was useless to talk of electric driving if the propeller could be driven by the engine, but the fact remained that a low-speed ship could not be driven by a high-speed propeller. If electric driving were adopted there was nothing to prevent the use of an engine running at 3,000 revs. per min. in a low-speed ship. In a particular instance he had obtained an estimate from makers of mechanical gear, and it turned out to have practically the same weight, price and efficiency as the electrical gear. There was no additional danger of breakdown because there was practically no additional complication. Nothing could be simpler than a squirrel-cage rotor, and he called attention to the fact that the energy was generated in the stationary portion of the machine, it was transmitted by cables that did not move, and it was utilised in the stator of the motor. It was sometimes more economical to employ two or three small generating sets, rather than one large one, as they were frequently more efficient. Moreover, each machine could be connected to its own coils of the motor, and was, therefore, completely independent of the others. Complicated switchgear was avoided, and since the motor coils were mutually non-inductive there was no fear of current being generated back into a machine which happened to be at rest. With regard to the chairman's suggestion of short-circuits, he pointed out that even if a short-circuit did occur it could have *no* serious consequences. The power of the engine was limited, and the only effect would be the production of a current two or three times greater than the normal, with a corresponding drop in voltage. This would produce nothing like the disastrous results associated with short-circuits on street mains designed for comparatively small currents, when there was practically unlimited power at the generating station. So far as he could gather, flooding of the motor did not make the least difference. Some time ago he made an experiment on an old continuous-current motor, which, of course, possessed the additional disadvantage of a commutator; this machine he put under water, and it ran quite sweetly all day. In reply to Sir William White, Mr. Mavor said that the voltage he employed was 2,000, but the pressure was quite immaterial.

The next Paper on the list was on "Electrical Steering," by Mr. B. P. Haigh. The problem is a difficult one because two very different conditions have to be fulfilled. On the one hand it is necessary to have a system capable of dealing with the power necessary to put the helm hard over in emergency in the shortest possible time, and, on the other, it must possess sufficient sensitiveness to enable an accurate course to be kept by moving the rudder promptly through small angles. So far as sensitiveness is concerned, it appears that electrical gears are an improvement on steam gears, partly owing to the rapid wearing of valves and the loss of economy when large sensitive valves are employed. In the author's system the motor is kept running and is provided with two magnetic clutches, one at each end of the shaft. Three slip-rings are provided on the motor shaft, one being common to both clutches and the others distinct. Current is carried from the slip-rings to the clutches by means of leads passing through a hole in the shaft. These leads are quite small, the magnetising current being only about ½ ampere. The actual friction surfaces in the clutches consist of steel and red fibre.

The discussion was opened by Mr. Worby Beaumont, who thought that there would be considerable inequality of performance of the fibre employed in the clutch; he also thought it undesirable to carry leads in the motor shaft. Sir William White expressed himself strongly in favour of electrical steering. He had recently designed a yacht in which everything was done by electricity. He rather thought that great sensitiveness of steering gear was sometimes a positive disadvantage, for it tempted a steersman to manipulate it much too frequently; indeed, it might even be a source of danger in the hands of a nervous person. For this reason, he strongly advised the installation of a helm indicator in every case, so that a steersman could see the immediate result of his movements. He would abolish all hunting gear, and give all orders from amidships. So far as sensitiveness and ease of control were concerned, the superiority of electric gear was undoubted. Prof. Dalby, who spoke next, said that the principal feature of Mr. Haigh's device was the clutch. He would like to know what was the coefficient of friction between the steel and fibre, and what was the pressure per square inch

Digitized by Google

In the course of his reply, Mr. Haigh said fibre was the best substance he had tried. The difficulty with wood was that it soon charred, and then made an intolerable squeaking noise. Fibre, of course, was very hygroscopic, and on this account would prove unreliable when the clearance was small, the clearance on his clutch being $\frac{1}{16}$ in. He had, however, got over the difficulty by boiling the fibre in oil, which effectually prevented any absorption of moisture. There was no appreciable slipping even when oil was present. He had purposely poured oil into the clutch and then closed it; for about a dozen revolutions it slipped, then the oil was squeezed out between the fibre segments, and it held quite well. He had not noticed any falling off of friction with temperature, nor was there any variation when the rudder was hard over. The power demanded by the motor was not sufficient to affect the lighting circuit. He did not think there was any danger incurred by putting the leads in the shaft of the motor. Very sensitive gear was never put on low-speed ships. In reply to Prof. Dalby, the author stated that the coefficient of friction of steel on fibre was about one-sixth, and the pressure he employed did not exceed 100 lb. per square inch.

Mr. T. F. Wall next read a Paper on "The Single-phase Repulsion Motor," but as it was of a type seldom heard at a British Association meeting, there was no discussion. It will be given in full in future issues of THE ELECTRICIAN.

Next came a Paper entitled "Some Preliminary Notes on a Study as to Human Susceptibility to Vibration," by Mr. W. Pollard Digby and Capt. A. Riall Sankey. The Paper described the results undertaken with a view to ascertaining what amount of vibration can be said to constitute a nuisance. The audience treated the matter as something in the nature of a joke, and some additional "standards of degree of vibration" were suggested informally. Apparently, certain members seemed to think that "excessive" was not a sufficiently violent adjective to describe some forms of nuisance, and although they did not put them forward at the meeting there is no doubt that many would be prepared to offer suggestions to the authors with a view to adding to the different degrees. Prof. Dalby said he thought no subject should be treated who had not just completed three months' holiday. Sir William White thought there must be some scientific standard of vibration; the human element varied so greatly as to make it quite hopeless otherwise. Prof. Petavel called attention to the effect of sound, which made observers think a vibration very much more serious than it really was.

The chairman then announced that Prof. E. Wilson had asked for his Paper on "Some New Aluminium Alloys" to be taken as read, and this concluded the business of the day. (This paper will be given in next week's issue of THE ELECTRICIAN.)

Monday, September 4th.

Sections A and G had a joint meeting this morning for the purpose of discussing "Aeronautics," and then split up again. The first Paper on the programme for Section G was by Prof. H. W. O. Howe, on "Recent Developments in Radio-telegraphy," and it attracted a large audience. The author gave an excellent, though brief, account of the modern practice of wireless telegraphy, and succeeded in making some difficult points quite clear by means of diagrams. Moreover, he had erected up an aerial from the Town Hall to the roof of the Municipal Technical College, in which the meeting was held, and was able to receive—among other things—the Paris and Norddeich time signals. By means of a telephone relay of the pattern designed by Mr. S. G. Brown and conical trumpets these signals were made audible to almost everyone in the room. Prof. Howe's Paper is published in full in the present issue of THE ELECTRICIAN, and we will, therefore, refer to it no further here.

Next on the list came a Paper by Capt. H. Riall Sankey, entitled "Portable Equipment for Wireless Telegraphy." However, instead of reading a Paper Capt. Sankey contented himself with showing a number of quite interesting slides relating to portable sets for use by troops in the field. The first set was intended for cavalry, the various parts being carried on the backs of horses. For example, one horse carried the petrol engine and alternator, another the sending and receiving apparatus, while a third carried the mast and aerial. The capacity of the alternator was 0·4 kw., and the range was 20 miles over mountainous country and 100 over water. Each animal's equipment was securely fastened to a saddle of special design, and in no case did the total weight exceed 180 lb. When fully extended the mast had a length of 60 ft., but as a directive aerial was employed it was necessary to carry two masts, the effective length of aerial being 350 ft. between masts. In order to preserve the insulation of the high-tension transmitting apparatus the latter was completely enclosed in a metal case. On taking this case from the horse's back, a double lid is opened, one serving as a writing desk and the other as a protection against rain, &c. Capt. Sankey mentioned that the time occupied in getting a station set up and working was only nine minutes, while the time occupied in taking it down and packing it up again was six minutes.

At the conclusion of Capt. Sankey's remarks there was only about a quarter of an hour available for discussion of both Papers, owing to a fixture having been arranged for 2 p.m., but even this proved more than sufficient. In reply to questions from Prof. Dalby, Prof. Howe stated that the Marconi trans-Atlantic work was carried on with a wave-length of 6,000 metres. He had ascertained this from his own observations. The minimum that he knew of was 300 metres, and he believed that the Admiralty kept all wave-lengths between 600 and 1,600 metres for themselves. The sharp tuning of the receiving station depended on the tuning of the transmitting station, for if the coupling were too tight, harmonics came in; it was impossible to tune to an explosion. This concluded the work of the Section for the day.

In the afternoon a most interesting display was provided by the Admiralty, by arrangement of the Commander-in-Chief, Admiral Sir A. W. Moore, G.C.B. Members of the Association were taken on board H.M.S. "Revenge" at the Dockyard and sailed out to sea some miles from the coast. An attack was then made on the vessel by about a dozen torpedo boats. These boats advanced on the "Revenge" at full speed, discharging torpedoes at her as they passed alongside. Next, four submarines advanced in line ahead, the first passing with conning tower out of water and driven by her petrol engines. The second advanced and dived just as she came alongside, this vessel and the remainder being driven by electric motors. The third dived gradually as she passed, and reappeared after passing. Finally, the fourth boat, which could be seen rather more than a mile away, dived and advanced on the "Revenge" with only her periscope showing. When she got within striking distance she fired a torpedo which gave the onlookers a decided thrill, as it struck the vessel with a plainly perceptible "bump." Still advancing, she fired a second, and then dived so that even her periscope disappeared. In a few seconds she reappeared, and her commander, who presently emerged from the conning tower, was greeted with a storm of applause. The "Revenge" then returned to the Dockyard, and members were unanimous in describing the display as quite the feature of the Portsmouth Meeting.

Tuesday, September 5th.

Some very interesting work was done in Section G this morning, when the respective merits of steam, suction gas and Diesel engines were discussed. Mr. W. T. Marshall commenced with a Paper on "Economical and Reliable Power Generation by Over-type Superheated Steam Engines." He remarked that owing to the introduction of internal combustion engines, steam-engine builders had been stimulated to produce steam plants having a fuel cost quite on a par with that of internal combustion plants, and possessing additional advantages in the nature of superior reliability, flexibility and over-load capacity. The so-called "over-type superheated steam engine" is a distinct reversion to the old portable type, and consists of a compound engine fixed on top of a tubular boiler, with a superheater in the smoke box. Air pump, feed

Digitized by Google

quite overshadowed by the disaster on the London County Council's system. These tramways, considering their size and the exceptional traffic difficulties, have been comparatively free from serious accidents, but that which occurred last week proved exceptionally disastrous. For the present the cause of the car leaving the rails is shrouded in mystery, and owing to the conflicting evidence as to the state of the rails it is likely to remain so. It is noticeable that the large majority of serious tramway accidents occur at more or less sharp curves in the track; and as the lay-out of such curves necessitates the negotiation of them by the cars at very low speeds it would seem desirable for all curves to be inspected by some authority with a view to possible alteration. Since tramcars have to compete with motor traffic, any reduction in speed would now be a serious handicap; but if present speeds are to be maintained it is essential that great attention should be paid to the maintenance of the track in a clean and good condition.

Production of Light.

THE production of light is one of the most fascinating of subjects, partly because we know so little of the ultimate phenomena underlying some of the processes of production, and partly because of the enormous possibilities that are yet open to the patient investigator. The present methods of producing light are extraordinarily inefficient, and yet during the last few years great advances have been made. The metal filament lamp, the flame arc lamp, the vacuum tube, operated either as a mercury arc or by an electric discharge, all indicate a movement in the right direction. A very great deal, however, yet remains to be done if we are to approach the efficiency of Nature, though certainly the station engineer does not wish this efficiency to be approached too closely. But we do not doubt that there are many investigators who are keenly anxious to produce a truly cold light, either by means of the electric discharge or by means of fluorescence, and thus to emulate the hitherto unrivalled efficiency of the firefly. The engineer wishing to approach this subject from the more theoretical standpoint finds himself at a disadvantage in that the subject in some respects is by no means simple, and further the literature on the subject is more or less scattered, so that it is not easy to find what has been done without spending a good deal of time in looking up various publications. We therefore think that our readers will welcome the series of articles, the first of which appears in our present issue, by Dr. R. A. HOUSTOUN, as they present the subject, although briefly, from many points of view.

The "Telefunken Zeitung."—We have received from Berlin a copy of the first number of this periodical, which is edited by Mr. H. Bredow, and is devoted to the interests of the Gesellschaft für Drahtlose Telegraphie. The present issue contains a photograph commemorative of the visit of the Emperor William to the Nauen station. There is also an historical article on the progress of the Telefunken Co. and other matters of current wireless interest.

Cable Interruptions.	Date of Interruption.
Assab—Perim	July 8, 1909
Latakia—Palura	May 26, 1910
Zanzibar—Mombasa	July 11, 1911
Sabang—Koetaradja	Aug. 18, 1911
Kotonou—Grand Bassam	Aug. 23, 1911
San Thiago—Bathurst	Sept. 4, 1911
Bathurst-Sierra Leone	Sept. 4, 1911

Electric Lighting of Westminster Abbey.—Westminster Abbey, which has been closed since March 31st on account of the Coronation, was opened on Tuesday last for the usual services. The lighting of the nave is now effected by electricity instead of by gas.

Telegraph Union Monument.—"The Times" announces that the International jury have chosen the design submitted by Signor Giuseppe Romagnoli, of Bologna, for the International Telegraph Union monument. The design represents Helvetia seated and having on either side figures representing Trade, Labour and the various professions.

London Electricity Supply Works Survey.—The Chief Commissioner of Metropolitan Police (Sir E. R. Henry) is having a survey made of the electricity supply works, power stations, gas works, &c., within the Metropolitan Police area, with the view of collecting information for the guidance of the police in future industrial disputes.

New Director of the Science Museum.—It is announced that Mr. F. C. Ogilvie, C.B., has been appointed Director of the Science Museum, and will hold this position in addition to his present office of Secretary for the Science Museum and Geological Survey and Museum. Mr. Ogilvie was educated at Aberdeen University and for a time held the position of Assistant Professor of Natural Philosophy, both at that University and at Edinburgh. He was director of the Edinburgh Museum of Science and Art from 1900 to 1903, and principal assistant secretary (Technology and Higher Education in Science and Art) of the Board of Education from 1903 to 1910.

"The Central."—The article of greatest interest in the current issue of this magazine is the first. It is devoted to an account of the life of Prof. Henrici, and is partly autobiographical and partly written by Mr. G. C. Turner. It is illustrated by three excellent photographs of Prof. Henrici at various times of his life, and of the Mechanics Laboratory which he founded at the "Central." A report is given of the complimentary dinner to Prof. Armstrong which was held on May 13th last, and there are also articles on "Lifeboat Launching Slipways"; on "The Training of Alluvial Rivers," by Mr. C. G. Smith, and "Notes upon Modern Simple Span Truss Bridge Construction," by Mr. R. O. Beit.

Deterioration of Insulation on Traction Motors.—The "Engineer" remarks that a tramway or railway motor is usually selected with reference to the work it has to do in propelling the car, with little regard to the extra work which is thrown upon it when braking. It is, therefore, often urged that, since a motor usually operates at a fairly high temperature under normal conditions, the extra load thrown upon it by electric braking is certain to produce more or less rapid deterioration of the insulation. With the latest type of track magnet, however, the current taken from the motors is a very small percentage of that required for rheostatic braking, and the increased heating due to braking with this type of magnet is practically nil. If, in addition, the motor fields are provided with solenoid operated shunts, excessive voltage rises cannot occur, and the usual objections to the use of the motors for electric braking are removed.

Smelting of Pig Iron by Electricity.—An official report on the experiments in the electric smelting of iron ore at Trollhätten has now been published by the Iron Institute of Sweden, which, in conjunction with the Government, provided the money to carry out the experiments on a commercial scale. On the basis of the selling price for the output of the furnace, agreed upon by the committee in charge of the operations, the experimental business was self-supporting, even for the short period of its duration, five months. It is stated that the results obtained warrant the opinion that the question of the economical smelting of iron in the electric furnace has been solved, and that perfection of the methods for handling the gases to secure a more effective circulation, if not their utilisation, will greatly enhance the results already obtained. It is hoped to reach the preliminary estimate of 3 tons of pig-iron per horse-power-year, although the results so far give only

Digitized by Google

2·7 tons. Trials have proved that the product of the electric furnace is as well adapted to the manufacture of steel as is the ordinary Swedish pig-iron.

The Need for Reform in our System of Chemical Training.—In an article on this subject in a recent issue of "Chemical Engineering and the Works' Chemist," the author remarks that too much time is at present given to the acquisition of detail, while too little regard is paid to the real object of scientific education, which is to develop the reasoning powers. Students should be taught chemistry so that they may be able to apply their knowledge intelligently in after-life. To think and to originate are infinitely more important for the man of science than simply to be a master of detail. Some of the cures proposed for this evil are worse than the disease. More attention should be paid to the value of scientific application and less to the results of "cramming." Graduation by research should be made the rule and not the exception, as this method would differentiate between the student who can simply cram facts and one who is capable of applying what he knows to useful purposes. What is above all things necessary, the author concludes, is proper instruction in applied chemistry and encouragement of students to take up applied chemical research. It must be borne in mind, too, that it is not possible to study technical chemistry in a college alone, and that a student should pass a period in works in order that he may gain the all-important experience of the conditions which obtain on a large scale.

Royal Engineer Cadets (2nd London Division).—We are informed that recruits are wanted for this Corps, and great efforts are being put forth to bring it up to its establishment. The Company at present in existence is a Fortress Company, but if the right kind of recruit is forthcoming in sufficient numbers, it is proposed to form a Communication Company. Youths between the ages of 13 and 18 years having a knowledge of electricity or telegraphy should therefore send in their names. The cadets are instructed in all branches of military engineering, and the training and instruction are of a very interesting character for any lad desirous of serving his country.

Cadets transferring to the Territorial Force from their Cadet Corps are excused their recruit drills, and service in a Cadet Unit after the age of 15 counts towards the Territorial Efficiency Medal. Recruits are enrolled between the ages of 13 and 18, and should apply at the Duke of York's Headquarters, Chelsea, S.W., on Monday and Friday evenings between 7:30 and 9 p.m. Full particulars can be obtained from Sergt.-Major G. D. Elms, R.E. (T.), 37, Langthorne-street, Bishop's Park, S.W. Col. Sir Howland Roberts, Bt., V.D., is the honorary Commanding Officer, and the officer in command of the Corps is Capt. Beeman, R.E. The Corps attended the annual training and camp this year with the Royal Engineers, 2nd London Division, at Shorncliffe, from the 7th to the 19th August, and worked with the sappers in building a redoubt and in constructing a trestle and double-lock bridge. The cost of uniform and equipment amounts to about 15s., and there is an entrance fee of 1s. Rifles, bayonets and brown Slade-Wallace equipment are supplied, and remain the property of the Corps.

The Noise of Motor Cars.—During the past few months correspondence has been taking place in several of our daily contemporaries regarding the noise made by drivers of motor vehicles, especially at night. As a result of this agitation, which from our own experience seems to be especially well-founded, the Commissioner of Police of the Metropolis has, with the concurrence of the Local Government Board, issued a circular dealing with the matter. He points out that while it is necessary for all motor drivers to give audible warning of their approach when there is possibility of danger, where the only danger is attributable to reckless speed the practice quickly develops into an avoidable nuisance. Attention is also called to the practice of using a "cut-out" and the employment of siren or multiple horns worked from the exhaust. It is quite certain, he points out, that unless some alteration is brought about by motorists of their own impulse there will be an insistent demand for repressive legislation. In these circumstances the Commissioner of Police thinks it advisable to call upon all owners and drivers of motor vehicles to do what is in their power to reduce the annoyance caused, especially at night, by the excessive use of the horn, or by the use of unsuitable devices, such as those above mentioned, for unnecessarily varying the timbre or intensifying the sound emitted. He feels sure that much may be done by concerted action on the part of owners and drivers of private cars to diminish the nuisance which is now so much complained of. From this circular it is evident that if this plain hint is not sufficient the Commissioner will use his powers to make a bye-law on the subject. The nuisance is of course primarily due to drivers of taxi-cabs and chauffeurs who are freed from the influence of their employers. Since, too, a silent motor-'bus is an assured fact, attention might also be paid to the excessive noise at present made by many of these vehicles.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Dr. R. Beattie contributes an article on "An Extension of Fischer-Hinnen's Method of Harmonic Analysis."

Dr. R. A. Houstoun contributes the first of a series of articles on "Studies in Light Production."

Our special correspondent gives an account of the Papers and discussions at the meeting of the British Association at Portsmouth. Abstracts of the following Papers which were presented at the meetings of the various Sections will be found elsewhere in this issue: "Electric Drives for Screw Propellers," by Mr. H. A. Mavor; "The Origin and Production of Corrugation of Tramway Rails," by Mr. Worby Beaumont; "Recent Developments in Radio-telegraphy," by Prof. G. W. O. Howe. The presidential address of Sir William Ramsay (of which an abstract appeared in our last issue) is discussed in our Leading Article.

The Trades' Union Congress has been held during the week at Newcastle-on-Tyne, and the president, Mr. W. Mullin, referred to the course adopted by the unions when legislation affecting the working classes is in preparation. He remarked that discussions between members of the Cabinet and accredited representatives of the unions had become a part of the regular programme. (We wonder is the same practical course adopted towards the masters). Mr. Mullin referred particularly to the Insurance Bill in this connection. He also referred to the recent series of so-called "strikes."

Shoreditch (London) Council have decided to adopt incandescent electric lighting in place of gas in the portion of their area north of Old-street.

Salford Corporation are recommended to carry out extensions and to effect improvements of their electricity supply undertaking at an estimated cost of £85,350.

The Port of London Authority have decided to provide four electric ambulances for the docks under their control.

An interesting report on methods of charging for electric current at Brighton has been prepared by the engineer and manager, Mr. John Christie. The report recommends the abolition of meter rents and the adoption of a flat rate of charge for all current supplied.

OBITUARY.

T. H. Riches.—We regret to record the death of Mr. Thomas Hurry Riches, locomotive superintendent to the Taff Vale Railway, which occurred at Cardiff on Monday last at the age of 65. Mr. Riches was a past-president of the Institution of Mechanical Engineers and for three successive years was also president of the South Wales Institute of Engineers. He served as chairman of the mechanical engineering section of the Franco-British Exhibition.

H. O. Wills.—We also regret to record the death of Mr. Henry Overton Wills, chancellor of the University of Bristol, which occurred at Kelston Knoll, Weston, near Bath, on Monday last. Mr. Wills took great interest in the formation of the university in Bristol, and went so far in practical sympathy as to subscribe £100,000 towards the project. When the charter was eventually granted Mr. Wills became the first chancellor of the new university.

PERSONAL NOTE.

On Monday Mr. W. Aitken left Liverpool by the s.s. "Megantic" for New York. Mr. Aitken will be absent from England for some time on business and pleasure.

APPOINTMENTS VACANT AND FILLED.

An Atlantic steamship company advertises for an assistant foreman electrician.

An assistant electrician is wanted for works in South Wales. Must be good wireman and able to take charge of installation during absence of electrician. See an advertisement.

INSTITUTIONS AND SOCIETIES.

Municipal Tramways Association.—The tenth annual conference of this Association will be held at Glasgow on Sept. 27, 28 and 29, under the presidency of Mr. James Dalrymple. The following preliminary programme has been arranged: On Wednesday, Sept. 27, there will be a reception in the City Chambers, and the Presidential Address will be delivered by Mr. Dalrymple. Papers will be read by Mr. W. Nelson and by Ald. J. H. Rodgers, the latter on "The Present Position of Municipal Tramways." In the evening the delegates will be the guests of the Corporation at dinner. On Thursday, Sept. 28, Papers will be read on "Car Meters" by Messrs. R. G. & J. G. Cunliffe, and on "Tramway Track—Methods of Construction and Maintenance," by representatives of the Glasgow, Manchester and Leeds Corporation Tramways. In the evening the Association dinner will be held. Friday, Sept. 29, will be devoted to excursions. The Executive Committee, it is announced, have acceded to the wish expressed by several tramway manufacturers to arrange for exhibits in connection with the meeting. For this purpose it is proposed to set apart a portion of the Newlands tramway depot of the Corporation tramways in Kilmarnock-road, in order that manufacturers and inventors may have an opportunity of exhibiting anything of interest. No charge will be made for the space allotted. Communications should be addressed to Mr. James Dalrymple, general manager, Glasgow Corporation tramways. The headquarters of the Association during the Conference will be at the Grand Hotel, Charing Cross, Glasgow.

EDUCATIONAL NOTICES.

University of London, University College.—The new session commences on Monday, Oct. 2. There are complete courses of study, extending over three years, in mechanical, electrical, civil and municipal engineering. Students desirous of entering the faculty of engineering, with the view of taking a full degree or diploma course, must have passed the matriculation examination, or some other examination accepted in its stead. There are also special diploma courses, and provision is made for post-graduate work and research. Intending students should communicate with the Provost as soon as possible, and full particulars may be obtained on application to the secretary, Mr. Walter W. Seton, M.A., Gower-street, W.C.

University of Manchester.—In the faculty of science complete courses of study extending over three years are arranged for the University degrees in civil, mechanical and electrical engineering. The equipment of the civil and mechanical engineering laboratories was completed last session, and the new electrical engineering laboratory will be opened next month. Prospectus, containing full particulars of the courses will be forwarded on application to the Registrar. The session commences on Oct. 2.

University of Edinburgh.—The next session opens on Oct. 10. The University provides complete courses in civil, mechanical and electrical engineering, qualifying for the degree of B.Sc. in engineering, and extending over a period of three years. Particulars of the entrance examination, scholarships, fees, &c., can be obtained from the Matriculation Office, The University, Edinburgh.

University of Bristol.—Prospectuses and particulars of the faculties of arts, science, medicine and engineering (civil, mechanical, electrical and motor car) and of the secondary training department, day training colleges, evening classes, halls of residence, scholarships and bursaries will be sent on application to the registrar, Mr. James Rafter. The session in the faculty of engineering commences Sept. 15 and in faculties of arts, science and medicine on Oct. 2.

Goldsmith's College (University of London).—At this college complete evening courses of instruction are provided in mechanical, electrical and constructional engineering, land surveying, fitting and machining, pattern-making and smithing. Students are prepared for the London University degree of B.Sc. in engineering, for the examinations of the Institution of Civil Engineers, Board of Education, and City and Guilds of London Institute, &c. Particulars from the Warden of the College, New Cross, S.E. The new session commences on Monday, Sept. 25, and enrolling will begin on the 18th inst.

University of Durham.—Armstrong College, Newcastle-upon-Tyne.—The 1911-12 session commences Sept. 25. There are departments of mechanical, marine, civil and electrical engineering, naval architecture, mining, metallurgy, agriculture, pure science, arts and letters. Particulars may be obtained from the secretary, Mr. F. H. Pruen, M.A.

University College of North Wales.—At this college a systematic course of instruction in electrical measurements and practical electricity is provided for students proposing to enter the electrical engineering profession. The physical laboratory is well equipped for practical work and the fee for the ordinary course is £17. 1s. per session. The next session commences in October.

Northampton Polytechnic Institute, Clerkenwell, London.—The full day courses in the theory and practice of mechanical and electrical engineering, and in electro-chemistry will commence on Oct. 2, and entrance examinations will take place on Sept. 27 and 28, at which five entrance scholarships will be offered. The courses for mechanical and electrical engineering include periods spent in commercial workshops, and extend over four years, and they also prepare for the degree of B.Sc. in engineering of the University of London. There are also full and partial day courses in technical optics. Particulars from the Principal, Dr. R. Mullineux Walmsley.

Sir John Cass Technical Institute.—Evening classes in physics and mathematics, chemistry and metallurgy are held at this Institute, and are designed to meet the requirements of those engaged in the electrical, chemical and metallurgical industries and in trades associated therewith. Facilities are also afforded for special and advanced practical work in well-equipped laboratories, both in the afternoon and evening. The classes in physics and mathematics prepare for the final B.Sc. examination of the University of London, and there are also special courses on general physics and electricity and magnetism for the Honours B.Sc., and on conduction in gases, radio-activity and colloids for science students. The new session begins on Monday, Sept. 25. Particulars of classes may be obtained at the offices of the Institute, Jewry-street, Aldgate, London, E.C., or on application by letter to the Principal.

Battersea Polytechnic (London, S.W.).—The new session commences on Monday, 25th inst. There are complete day college courses in civil, mechanical and electrical engineering, extending over three or four years. These courses are suitable for preparing for the B.Sc. (Eng.) of the University of London, the Associateship examination of the Institution of Civil Engineers, &c. There are also evening classes in electrical technology, electrical design and power distribution, theory of machines, hydraulics, heat engines, strength of materials, &c. Further particulars can be obtained from the Secretary.

Borough Polytechnic Institute.—A four years' course of instruction in electrotechnics is provided at this Institute. There are also classes in electric wiremen's work, and elementary and advanced courses in electrical design and workshop drawing. The head of the department is Dr. John Henderson, D.Sc., F.R.S.E., A.M.I.E.E. Prospectuses, containing further particulars and detailed syllabus, from the Principal, Mr. C. T. Millis, Borough-road, S.E. The session begins on 25th inst.

Electrical Standardising, Testing and Training Institution.—This institution has two departments—a training department and a standardising and testing department. The training department provides students with a thorough course of instruction (theoretical and practical) in electrical and mechanical engineering. The full course occupies four years, and is so arranged that the first and third years are spent at Faraday House, the second at engine manufacturers, and the fourth year at electrical manufacturers or a power house. The principal is Mr. Alex. Russell, M.A., D.Sc., M.I.E.E., and he is assisted by a capable staff of lecturers. There are well equipped laboratories for practical work. The Michaelmas term begins on the 25th inst. Prospectuses containing particulars of fees, &c., from the Secretary, Faraday House, Southampton-row, W.C.

ARRANGEMENTS FOR THE WEEK.

THE LONDON ELECTRICAL ENGINEERS.
Officer Commanding, Col. H. M. Leaf.

The following orders have been issued:—

Head-quarters will be closed for instruction, but will be open for office work as under until further orders:—

Monday to Friday, 10 a.m. to 4 p.m.
Saturday, 10 a.m. to 12 noon.

ELECTRIC DRIVES FOR SCREW PROPELLERS.*

BY H. A. MAVOR.

Summary.—The author first discusses the difficulties in the application of steam turbines and internal combustion engines to screw propellers, and he considers that electric transmission is eminently suitable for adapting these prime movers to the propeller. After referring briefly to his system of electric propulsion, he gives several examples of vessels to which it has been proposed to be applied.

The problems of marine engineering have until recent years been solved exclusively by the application of various forms of the reciprocating steam engine, and the power, speed, form and general arrangement of power-driven vessels have been developed in connection with this means of propulsion.

The advent of other appliances has opened up new lines of development, and in certain departments there is evidence of need for intermediate devices between the power-producing and the power-absorbing elements. The necessity for these devices arises when the properties of the propeller in respect of rate of revolution are incompatible with those of the power generator.

This incompatibility is most conspicuous in vessels which have to operate at relatively low speeds. An examination of the conditions which have emerged in the development of marine propulsion soon shows that the incompatibility is not accidental, or due to imperfections in the design, construction or use of the propelling equipment, but that it is associated with the essential properties of the substances and appliances with which we have to deal.

It may be said in general terms that high efficiency is associated with low rate of revolution of the propeller, while in the steam turbine high rates of revolution are essential to the most economical use of the steam. Internal-combustion engines have speeds more nearly approximating those of reciprocating steam engines, but here also there is a tendency to speeds higher than are convenient or economical from the propeller standpoint.

In addition to those fundamental incompatibilities arising from causes out of the reach of direct accommodation, there are other conditions which limit the direct application of engine to propeller.

The draught, beam and form of the vessel limit the area of the propeller. The traffic for which the vessel is designed influences the determination whether one, two or more propellers are to be used, and the speed, size and form of the vessel determine limits to the designer's choice. All these considerations taken together frequently fix the diameter, pitch and thrust of the propeller, and, within very narrow limits, also the rate of revolution.

Now this rate of revolution is not always the most favourable for the power generator, and the designer is in such cases compelled to resort to new expedients if he is to attain the standard of efficiency in power generation which has been set by results attained on land. At the present moment the economy of power production in the best practice on land is considerably in advance of what has been done at sea. The principal reason for the better economy of the land work is the higher rate of revolution of the power generator when untrammelled by propeller conditions.

There are cases where the special limitations in respect of dimensions and weights permissible for the machinery are such as to preclude the use of any intermediate mechanism between the prime mover and the propeller.

In the ship whose voyage is short, whose speed is high, displace-

Digitized by Google

ment small and propeller efficiency as good as is attainable and the quantity of fuel carried small relative to the weight of the machinery, the possible economy in fuel may be insufficient to warrant any increase in the weight of machinery; or, to put the case otherwise, it is advisable to sacrifice economy in fuel to keep down the weight of the equipment—*e.g.*, a vessel running one-day voyages, and burning 50 tons of coal, could not possibly submit to an increase in weight of machinery in excess of the coal-saving, because such increase would increase the displacement, and therefore the power necessary to drive the vessel.

If, on the other hand, the vessel make a 10-day voyage, and the saving in fuel carried amount to 10 tons per day, a considerable increase in weight of machinery might be associated with decreased displacement and a substantial all-round economy.

Various methods of making the required adaptation of generator to propeller are at present under trial. For this, mechanical gearing by toothed wheels or hydraulic transmission may be considered serious competitors with electric transmission, but for large powers it seems reasonable to expect that electric transmission, which is already developed for this very purpose on land, is likely to find an equally useful field where the conditions are such as to require an intermediate device at sea. The cost, weight and efficiency of electric transmission compare favourably in the examples which have been examined with either of the two competing methods.

are attainable in a reciprocating steam engine connected direct to the propeller, and the electric motor is applicable to powers for which there is no possibility of using anything in the nature of reversing gears or clutches.

The property of combining the power of more than one engine for application to one or more propellers is the special feature of the author's inventions as distinguished from the ordinary methods of electrical engineering. Engines of different types, sizes and rates of revolution can have their powers combined without interconnection of their electric circuits, and without risk of mistake or error. An oil engine at 100 revs. per min. may be running the vessel at low speed, and a steam turbine running at 20 times the speed may be jointly applied to the propellers without any complication of the electric equipment. Each unit does its own work independently.

The advantage of such an equipment in vessels which are required to operate under varying load conditions is evident. Without subdivision of the power units the whole of the main machinery must be in motion while the ship is in motion.

At speeds reduced below its normal rate of revolution the turbine is even less economical than the steam engine. Subdivision into high-pressure, low-pressure and intermediate elements has been carried out in certain steam equipments, but this results in a somewhat complicated and inconvenient system of piping, because the steam has to be led from one part of the system to the other across the

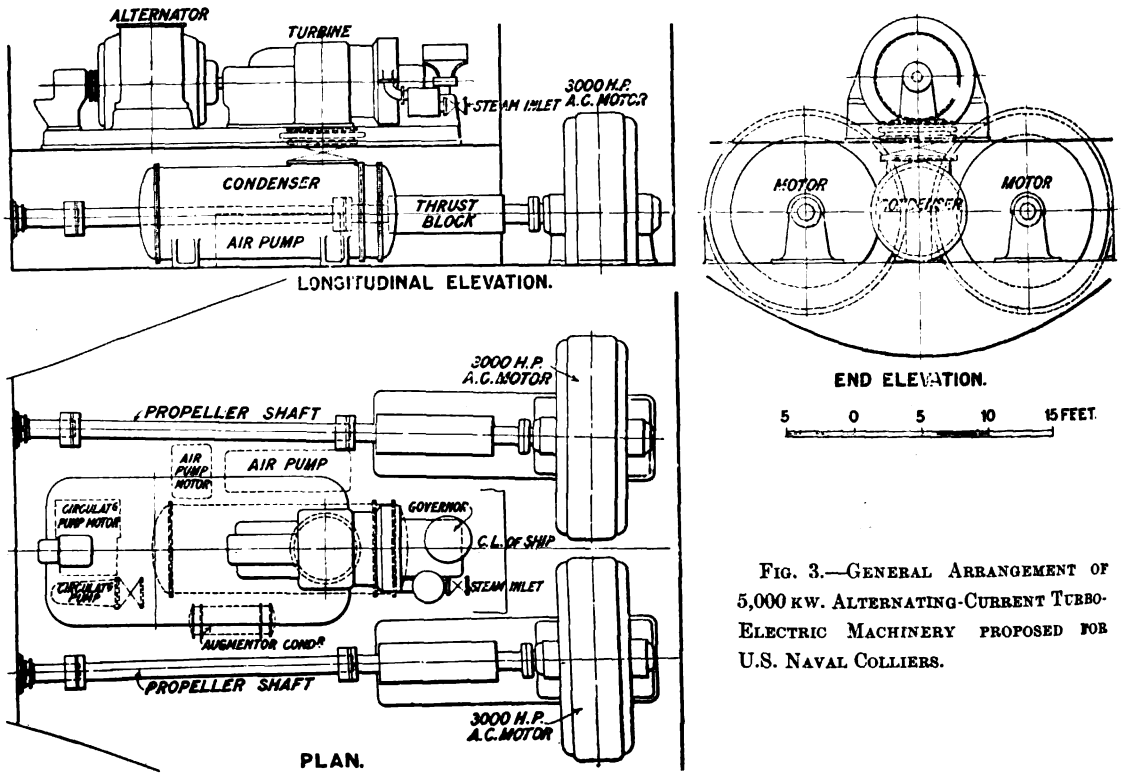

FIG. 3.—GENERAL ARRANGEMENT OF 5,000 KW. ALTERNATING-CURRENT TURBO-ELECTRIC MACHINERY PROPOSED FOR U.S. NAVAL COLLIERS.

There are other important qualifications of electric transmission in which it stands altogether unrivalled. The most important of these qualifications are:—

It provides a ready means of reversing the direction of rotation of the propeller without changing the direction of rotation of the power generator.

The electric transmission also provides means for changing the speed ratio between generator and propeller, so as to permit of the power of the generator being developed under the most favourable conditions at all speeds of the ship.

Lastly, it provides means for applying the power of one or more engines to one or more propellers, so that the power generating units may be so disposed as to give the highest efficiency, and when they are not required they can be stopped. These properties of the electric transmission supply exactly what is required to render steam turbines, and also internal-combustion engines, completely adaptable to the purpose required.

Power generators give their best efficiency when full speed of rotation is maintained, even when running below full power. It is therefore advantageous to keep the engine revolutions within the range of governor control while the required speed change is accomplished by electric combinations.

The properties of the electric motor lend themselves well to the requirements of manœuvring. The rate of reversal is under perfect control. The possibilities of rapid and certain action are more than

vessel. In the electric system each unit can be self-contained, and disposed in the manner best suited to a convenient arrangement of the engine room. The size of the individual units can be adjusted to suit the powers required at the different working speeds, or they may be duplicate and interchangeable.

A few examples of application of the system are here presented, together with a description of a small vessel built to demonstrate and illustrate the principles of operation and to provide experience in the use of the plant. In all cases alternating three-phase currents are used and interlocking devices connect mechanically the main reversing switches with the exciting switches so that no change can take place in the connections while they are passing currents.

DESCRIPTION OF THE TURBO-ELECTRIC STEAMSHIP "FRIEDA" (FOR AMERICAN OWNERS).

This vessel has been specially designed for the transport of bulk freights between the Gulf of Mexico and New York City. The vessel is to be 300 ft. long and will carry a dead weight of, approximately, 5,000 tons at a mean loaded speed of 12 knots at sea.

The propelling machinery is aft, and consists of a turbo-electric outfit for three-phase 50 cycles when running at 3,000 revs. per min. The turbine is supplied with steam at a pressure of 200 lb. per square inch at the stop valve.

This electric generating plant is arranged on foundations on a platform deck in the engine room and the condensing plant in the engine-

Digitized by Google

room hold. The condenser is fitted with a vacuum augmentor, and is suitable for dealing with the full load quantity of steam from the turbine. The vacuum obtained will be 28½ in., with cooling water about 85°F. The condensing plant consists of a vacuum condenser, three-throw air pumps and centrifugal pumps with electric motor drives.

The current is led to a three-phase motor, which is keyed direct to the main propeller shaft, and is capable of developing 1,900 B.H.P. at a speed of about 84 revs. per min. The steam is generated in two Scotch boilers, with Howden's forced draught and liquid fuel burners.

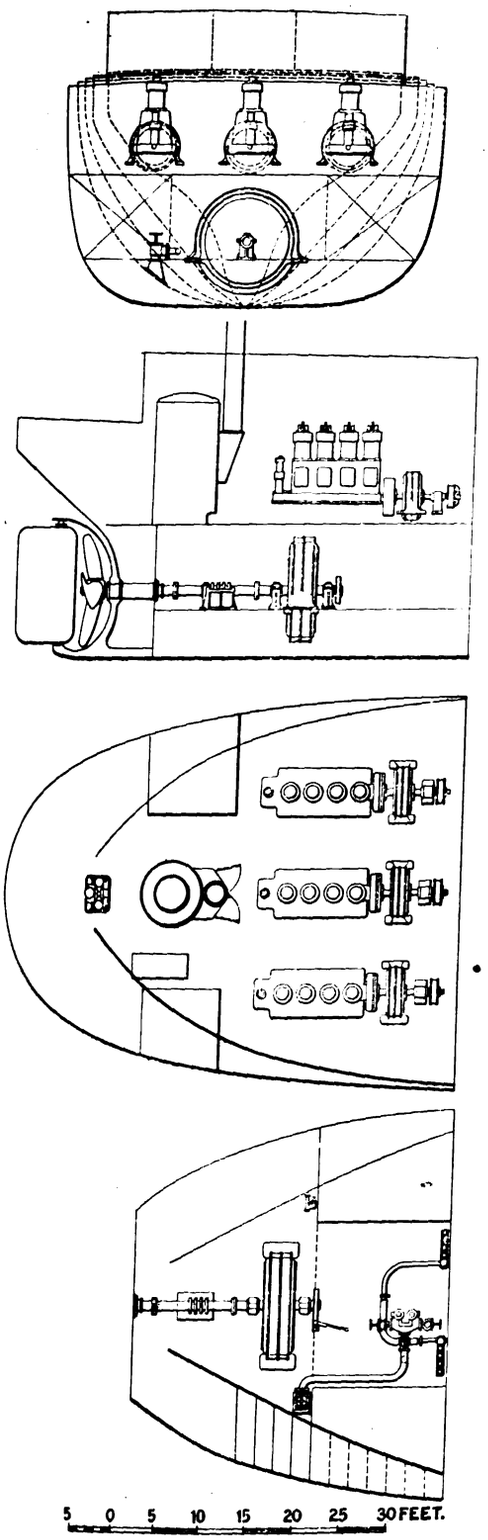

FIG. 4.—PROPOSED ARRANGEMENT OF OIL-ELECTRIC PROPULSION FOR LAKE STEAMER, 250 FT. BY 42 FT. 6 IN. BY 19 FT.

This installation costs and weighs less than the normal equipment. The coal-saving is over 10 tons per day.

The design of the ship itself presents many novel features not germane to the subject under review. This design was prepared by John Reid & Co., 17, Battery-place, New York.

OIL ELECTRIC TANK BARGE FOR CANADIAN SERVICE.

Fig. 4 shows the application of the system to the propulsion of a 245 ft. Canadian canal type tank barge.

The equipment consists of three separate units of Diesel non-reversible oil engines, each capable of developing 200 shaft H.P., and directly connected to an alternating-current generator. The currents from one or all of the units are respectively led to the separate windings of a three-phase motor keyed to the main propelling shaft and operating a single slow-turning screw.

The great advantage and economy of this system consists in being able to run at full power or at one-third power using one or three engines at full-load economy at will, thus providing for an economical operation impossible with any other propulsive system. The fact that non-reversible oil engines are used, running under governor control, greatly simplifies the maintenance and operation.

The control is operated by a low-tension interlocking switch, operated by an ordinary engine-room telegraph stand located in the pilot house, so that the manœuvring of the vessel is at all times in the hands of the navigating officer. This equipment increases the cost of the ship about 10 per cent. above the normal, but the carrying capacity is very largely increased.

MARINE TURBO-ELECTRIC INSTALLATION PROPOSED FOR U.S. NAVY COLLIERS.

The installation illustrated in Fig. 3 shows a marine turbo-electric installation submitted to the U.S. Navy Department for adoption in one of the four large colliers recently given out to contract.

It consists of a steam turbo-alternator of 5,000 kw. capacity with condensing plant; the current is led to two motors, one being keyed to each propeller shaft. The machinery is right aft in the vessel; the steam is generated by Scotch boilers.

The vessels in which it is proposed to instal this machinery are 525 ft. long, and will carry a dead weight of 12,500 tons of coal, at a speed of 14 knots at sea. Here again the cost, weight and economy are better than can be shown with the normal reciprocating-engine equipment.

AN EXTENSION OF FISCHER-HINNEN'S METHOD OF HARMONIC ANALYSIS.

BY R. BEATTIE, D.SC.

Amongst methods of determining the several coefficients in Fourier's expression

$$y = A_0 + A_1 \sin\theta + A_2 \sin 2\theta + A_3 \sin 3\theta + \ldots + B_1 \cos\theta + B_2 \cos 2\theta + B_3 \cos 3\theta + \ldots \quad (1)$$

for a single-valued periodic curve, one of the most useful is Fischer-Hinnen's development of the old principle of selected ordinates.* In order to find the coefficient of a harmonic of the nth order by Fischer-Hinnen's method, $2n$ equi-distant ordinates, spaced a distance π/n apart, are erected, the initial ordinate being at a distance $\pi/2n$ from the origin, or at the origin itself, according as a sine coefficient or a cosine coefficient is desired. The ordinates thus drawn are added together, the signs of all the ordinates of even number being reversed and the mean is taken. Calling S_n the mean of the sine-spaced ordinates, and C_n the mean of the cosine-spaced ordinates, then

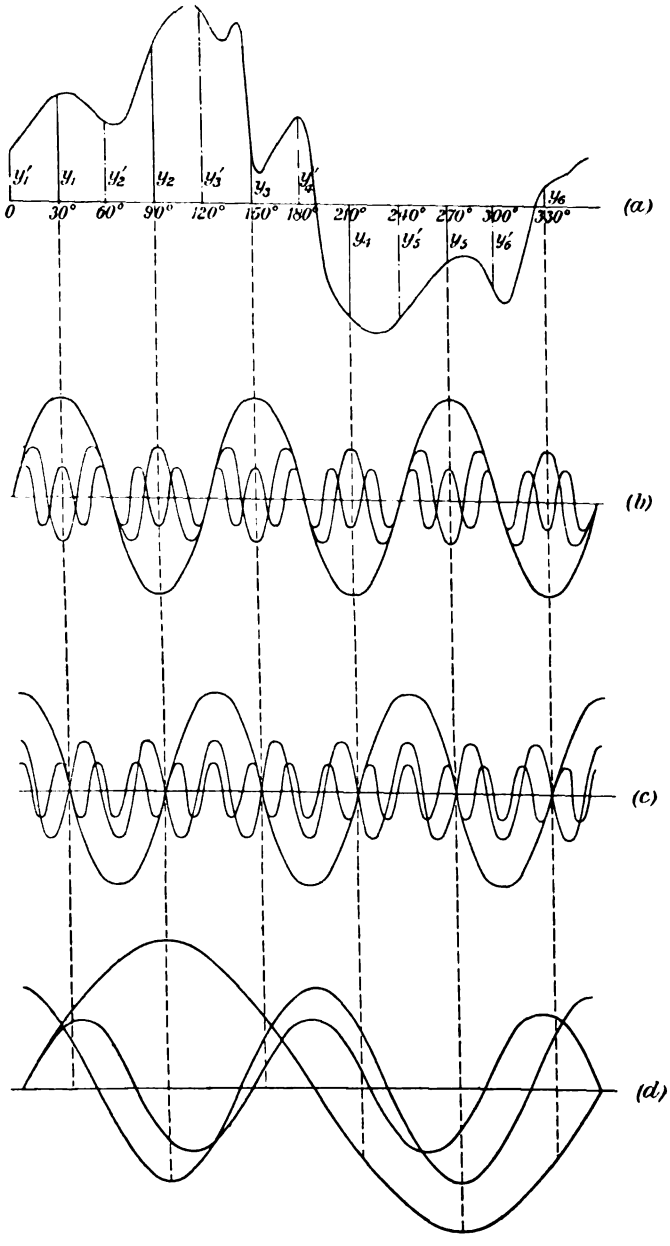
$$S_n = A_n - A_{3n} + A_{5n} - A_{7n} + \&c. \quad (2)$$
$$C_n = B_n + B_{3n} + B_{5n} + B_{7n} + \&c. \quad (3)$$

The truth of this result for a particular case is readily apparent from Fig. 1. This figure shows Fischer-Hinnen's construction for determining the coefficients A_3 and B_3 of the curve represented, the sine-spaced ordinates y_1, y_2, y_3, &c., being erected at distances 30, 90, 150, 210, 270 and 330 deg. respectively from the origin, and the cosine-spaced ordinates

* Fischer-Hinnen, "E.T.Z.," Vol. XXII., p. 396, 1901; "Elektrotechnik u. Maschinenbau," Vol. XXVII., p. 335, 1909. For references to earlier work on similar lines *see* Burkhardt, "Encyklopädie der Mathematischen Wissenschaften," Band II., Theil 1, p. 642; also Darwin, "Engineering," July 14, 1911, p. 81. [Since the foregoing was written, a Paper by Prof. S. P. Thompson has appeared, which should be consulted ("Proc." Phys. Soc., Aug., 1911, p. 334). This Paper, although entitled "A New Method of Harmonic Analysis," is really nothing more than an account of Fischer-Hinnen's method and contains no new developments.]

Digitized by Google

y'_1, y'_2, y'_3, &c., at distances 0, 60, 120, 180, 240 and 300 deg. respectively. It is seen that the successive sine-spaced ordinates cut the 3rd, 9th, 15th, &c., sine harmonics at their crest values, which are, of course, alternately positive and negative, whereas they cut the 3rd, 9th, 15th, &c., cosine harmonics at their zero values. Further, the sum of the intercepts of the sine-spaced ordinates with all the remaining harmonics, even or odd, sine or cosine, when taken over a whole period with alternate signs reversed, vanishes. Hence the average value of y_1, y_2, y_3, &c., with alternate signs reversed is equal to $A_3-A_9+A_{15}-$ &c. Similarly, the average value of the cosine-spaced ordinates y'_1, y'_2, y'_3, &c., with alternate signs reversed, is equal to $B_3+B_9+B_{15}+$ &c.



(*a*) Original Curve. (*b*) 3rd, 9th, 15th, &c., sine components. (*c*) 3rd, 9th, 15th, &c., cosine components. (*d*) All the even and all the remaining odd sine and cosine components including the constant term.

FIG. 1.—ILLUSTRATING HARMONIC ANALYSIS OF CURVE BY FISCHER-HINNEN'S 2*n*-ORDINATE METHOD.

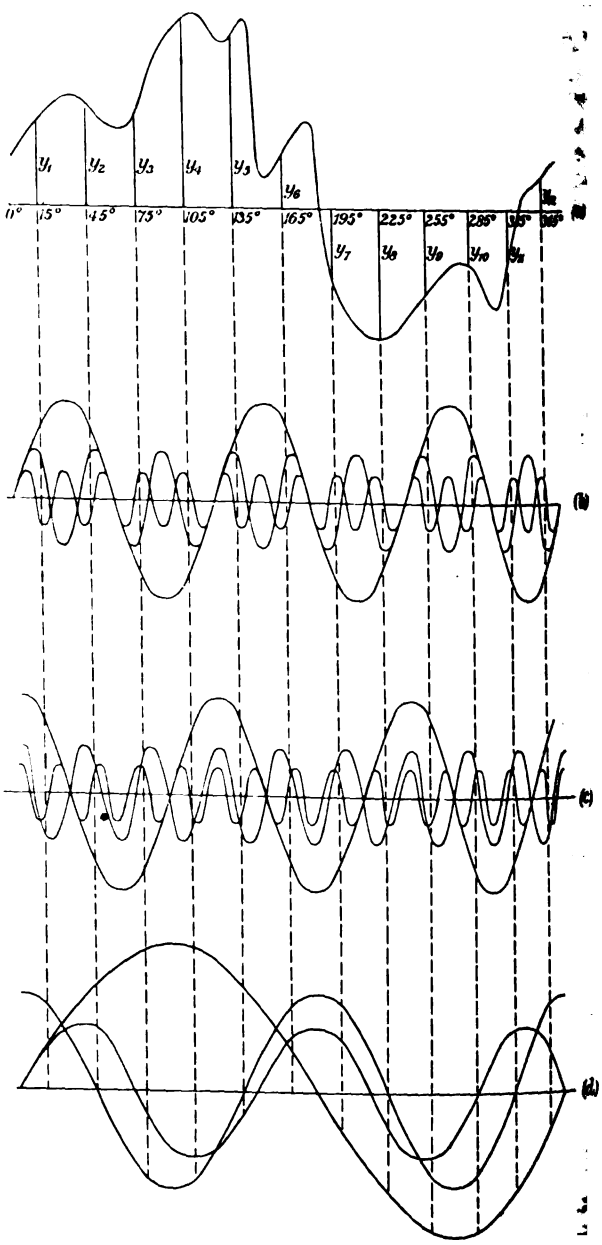
A disadvantage inseparable from Fischer-Hinnen's method is that it does not directly give the value of the harmonic sought, except in the special case where all the odd multiples of that particular harmonic are either absent or negligibly small. In practice, when evaluating higher harmonics, we are often certain, or can safely assume, that this is so, and the method is then specially serviceable. When evaluating lower harmonics, however, the absence of odd multiple harmonics cannot be taken for granted, and a process of elimination must therefore be resorted to. Thus suppose we know that, as in alternating-current wave-forms for instance, there are only odd harmonics present, and also that all harmonics of higher order than, say, the 15th are absent or negligible. We can then write

$$\left.\begin{aligned} &S_{15}=A_{15},\ S_{13}=A_{13},\ S_{11}=A_{11},\ S_9=A_9,\ S_7=A_7,\\ &S_5=A_5-A_{15},\ S_3=A_3-A_9+A_{15},\\ &S_1=A_1-A_3+A_5-A_7+A_9-A_{11}+A_{13}-A_{15} \end{aligned}\right\} \quad \ldots \quad (4)$$

from which we readily deduce

$$\left.\begin{aligned} &A_{15}=S_{15},\ A_{13}=S_{13},\ A_{11}=S_{11},\ A_9=S_9,\ A_7=S_7,\\ &A_5=S_5+A_{15},\ A_3=S_3+A_9-A_{15},\\ &A_1=S_1+A_3-A_5+A_7-A_9+A_{11}-A_{13}+A_{15} \end{aligned}\right\} \quad \ldots \quad (5)$$

A similar scheme of elimination can be drawn up for the cosine terms.



(*a*) Original Curve. (*b*) 3rd, 9th, 15th, &c., sine components. (*c*) 3rd 9th, 15th &c. cosine components. (*d*) All the even and all the remaining odd sine and cosine components including the constant term.

FIG. 2.—ILLUSTRATING HARMONIC ANALYSIS OF CURVE BY 4*n*-ORDINATE METHOD.

When there is no certainty that all harmonics above a certain order are either absent or diminish very rapidly in value, Fischer-Hinnen's method, while still applicable, becomes laborious and comparatively useless. Even in these circumstances, however, the scope of the method can, by a simple development, be considerably extended and its accuracy appreciably increased without departing from the general principle involved.

A Modified or 4n-Ordinate Method.—Improvements on Fischer-Hinnen's method may aim at (i) reducing the errors

Digitized by Google

due to accidental irregularities in the curve to be analysed, (ii) reducing the number of included higher harmonics. Both these ends can be attained by increasing the number of ordinates employed. The extent to which the number of ordinates can be increased is limited by the condition that multiplications or divisions must not be introduced further than what is required in averaging ordinates. It is, however, possible to double or even treble the number of ordinates without sensibly departing from this condition.*

Suppose, for example, that we wish to find the coefficient of the nth sine harmonic. Instead of erecting $2n$ equi-distant ordinates, as in Fischer-Hinnen's method, we erect $4n$ ordinates spacing them a distance $\pi/2n$ apart, the initial ordinate of the series being at a distance $\pi/4n$ from the origin. These ordinates we add together, taking them in pairs, and reversing the signs of alternate pairs. That is to say, the signs of the 1st and 2nd, 5th and 6th, 9th and 10th, &c., ordinates are left unchanged, those of the 3rd and 4th, 7th and 8th, 11th and 12th, &c., ordinates are reversed, the scheme of reversal being indicated by $++--++--$&c. The average ordinate obtained in this way when multiplied by $\sqrt{2}$ gives a quantity which we shall denote by S'_n. It is then easy to show that

$$S'_n = A_n + A_{3n} - A_{5n} - A_{7n} + A_{9n} + A_{11n} - A_{13n} - \&c. \quad . \quad (6)$$

To get the corresponding cosine term the ordinates are drawn precisely as for the sine term, with the initial ordinate at a distance $\pi/4n$ from the origin. The only difference lies in the way the ordinates are added up. In doing this the signs of the first and last, 4th and 5th, 8th and 9th, &c., ordinates are left unchanged, whilst the signs of the 2nd and 3rd, 6th and 7th, 10th and 11th, &c., ordinates are reversed, the scheme of reversal being therefore indicated by $+--++--$&c. The average ordinate thus obtained when multiplied by $\sqrt{2}$ we shall denote by C'_n. We then have

$$C'_n = B_n - B_{3n} - B_{5n} + B_{7n} + B_{9n} - B_{11n} - B_{13n} + \&c. \quad . \quad (7)$$

In proof of (6) and (7) it will suffice to take the particular case represented in Fig. 2. Here the ordinates are drawn according to the modified method for determining the 3rd sine component of the curve shown, the ordinates, 12 in number, being spaced 30 deg. apart, with the initial ordinate 15 deg. from the origin. It is seen that these ordinates cut the 3rd sine harmonic and all odd multiples of the 3rd sine harmonic in the same relative position—viz, 45 deg. from the maximum, the 45 deg. being reckoned on the scale of the harmonic considered. It is likewise seen that the sum of the intercepts with these harmonics, taken with signs reversed in pairs according to the scheme $++--++--$&c., is equal to $\frac{12}{\sqrt{2}}(A_3 + A_9 - A_{15} - A_{21} + A_{27} + A_{33} - \&c.)$. At the same time the sum of the intercepts with all the remaining harmonics, of whatever order or denomination, when taken over a complete period with signs reversed in pairs, is seen to vanish. It follows that $\sqrt{2}$-times the average value of the ordinates y_1, y_2, y_3, &c., with signs reversed in pairs, must equal $A_3 + A - A_{15} - A_{21} + A_{27} + A_{33} - \&c$. From this the general result of (6) can readily be inferred, as also, by similar reasoning, that of (7).

It will be observed that the result obtained by averaging ordinates on the above plan still contains all harmonics which are odd multiples of the harmonic sought. These included harmonics have, therefore, to be eliminated by proceeding as in the schemes (4) and (5) already outlined for Fischer-Hinnen's $2n$-ordinate method. Thus, taking the previously chosen case of a curve containing odd harmonics only and none higher than the 15th, we have

$$\left.\begin{array}{l} A_{15} = S'_{15},\ A_{13} = S'_{13},\ A_{11} = S'_{11},\ A_9 = S'_9, \\ A_7 = S'_7,\quad A_5 = S'_5 - A_{15},\ A_3 = S'_3 - A_9 + A_{15}, \\ A_1 = S'_1 - A_3 + A_5 + A_7 - A_9 - A_{11} + A_{13} + A_{15} \end{array}\right\} \quad . \quad . \quad . \quad (8)$$

with a similar scheme for the cosine coefficients.

A Combined or 6n-Ordinate Method.—Taken by itself, the modification of Fischer-Hinnen's method just described has certain minor advantages. These arise in part from the increased number of ordinates employed, which helps to eliminate errors due to accidental irregularities, and in part from the fact that the same ordinates serve both for the sine and cosine components. In practice, however, it does not always lead to results that are conspicuously superior to those obtained by Fischer-Hinnen's $2n$-ordinate method. The improvement hinted at in an earlier paragraph is the outcome of combining the results of the $2n$ and $4n$-ordinate methods.

As has been pointed out, the result obtained in attempting to evaluate a given coefficient, say A_n, by Fischer-Hinnen's $2n$-ordinate method includes the coefficients A_{3n}, A_{5n}, A_{7n}, &c. The result obtained in attempting to estimate the coefficient A_n by the modified method also includes the same coefficients A_{3n}, A_{5n}, A_{7n}, &c., only they enter into the result in a different way. Thus we have

$$S_n = A_n - A_{3n} + A_{5n} - A_{7n} + A_{9n} - \&c.,$$

by the $2n$-ordinate method, and

$$S'_n = A_n + A_{3n} - A_{5n} - A_{7n} + A_{9n} + \&c.,$$

by the $4n$-ordinate method. Hence, by taking the mean of the results of the two methods we can eliminate a large number of the higher included harmonics, and thus obtain a more

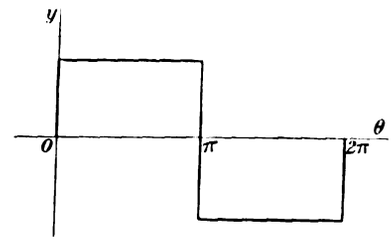


FIG. 3.—RECTANGULAR WAVE SHAPE.

accurate result. Calling the mean of the results for the nth sine coefficient S''_n, where $S''_n = (S_n + S'_n)/2$, we have, in fact,

$$S''_n = A_n - A_{7n} + A_{9n} - A_{15n} + A_{17n} - \&c. \quad . \quad . \quad . \quad . \quad (9)$$

Similarly, if we call C_n'' the mean of the results for the nth cosine coefficient, where $C''_n = (C_n + C'_n)/2$, then

$$C''_n = B_n + B_{7n} + B_{9n} + B_{15} + B_{17n} + \&c. \quad . \quad . \quad . \quad (10)$$

Obviously this process (which may be described as a $6n$-ordinate method, since it involves the measurement of $6n$ separate ordinates) gives directly a close approximation to the true value of any harmonic other than the fundamental, since no component of an order lower than seven times that of the harmonic sought is included in the result. To eliminate the few included harmonics that do remain we proceed as before. Thus for a curve containing odd harmonics only, of which the 21st and higher harmonics are assumed to be absent, we have

$$\left.\begin{array}{l} A_{17} = S''_{17},\ A_{15} = S''_{15},\ A_{13} = S''_{13},\ A_{11} = S''_{11}, \\ A_9 = S''_9,\quad A_7 = S''_7,\quad A_5 = S''_5,\quad A_3 = S''_3, \\ A_1 = S''_1 + A_7 - A_9 + A_{15} - A_{17} \end{array}\right\} \quad . \quad . \quad (11)$$

with a similar scheme for the cosine coefficients.

To illustrate the superiority of the $6n$-ordinate method we may apply it to analyse the rectangular wave-shaped curve of Fig. 3. This curve is known to possess a large number of sine components of odd orders and no cosine components. The amplitude of the components, moreover, decreases very slowly, and the curve therefore affords a severe test of the accuracy of any method of harmonic analysis. Representing the crest value of the curve by 1, its equation as a Fourier series is

$$y = \frac{4}{\pi}(\sin\theta + \tfrac{1}{3}\sin 3\theta + \tfrac{1}{5}\sin 5\theta + \tfrac{1}{7}\sin 7\theta + \&c.).$$

* Fischer-Hinnen's and similar methods of harmonic analysis are examples of approximate integration by averaging a finite number of ordinates. This method of integration and its limitations are discussed by Bruns in his book "Grundlinien des Wissenschaftlichen Rechnens" (Leipzig: B. G. Teubner, 1903). Amongst other examples he considers the evaluation of Fourier's coefficients and (Chapter VII., §§ 85 and 86) gives rules applicable to the general case in which the number of ordinates is made equal to $4m$, where m is any integer. The special advantage of choosing a number of ordinates divisible by 4 is pointed out by Bruns, and much of what follows in the present article might be deduced from his rules by putting m equal to the order of the harmonic sought, or to twice that order.

If we analyse the curve by the $2n$-ordinate method we get

$$y=\sin\theta+\tfrac{1}{3}\sin 3\theta+\tfrac{1}{5}\sin 5\theta+\tfrac{1}{7}\sin 7\theta+\text{ \&c.},$$

and by the $4n$-ordinate method

$$y=1{\cdot}41(\sin\theta+\tfrac{1}{3}\sin 3\theta+\tfrac{1}{5}\sin 5\theta+\tfrac{1}{7}\sin 7\theta+\text{\&c.}).$$

Both these results, which are obtained without having recourse to elimination, are seen to be hopelessly wrong, and equally so for the higher harmonics as for the lower. If, however, we take the mean we get

$$y=1{\cdot}21(\sin\theta+\tfrac{1}{3}\sin 3\theta+\tfrac{1}{5}\sin 5\theta+\tfrac{1}{7}\sin 7\theta+\text{\&c.})$$

which for many practical purposes may be accepted as sufficiently correct.

Diagrams for Use with Fischer-Hinnen's Method.—Fischer-Hinnen's method and its modifications have the merit that they can be carried out by the direct addition of ordinates as measured on the curve itself without the use of tables or adventitious aids of any kind. The application of the methods is greatly facilitated, however, by the use of specially prepared diagrams of suitably graduated scales similar to those described by the writer in THE ELECTRICIAN for June 9, 1911.

In the case of Fischer-Hinnen's $2n$-ordinate method, for instance, the diagram for determining an nth sine coefficient would consist of $4n$ equi-spaced vertical scales erected at successive distances of $\pi/2n$, π/n, $3\pi/2n$, $2\pi/n$, $5\pi/2n$ . . . &c., measured from one end of a common base-line. The units of the successive scales would be made equal in length to ± 1, ∞, ∓ 1, ∞, ± 1, ∞, &c., where the upper signs refer to the scales above the base-line and the lower scales to those below. The even-numbered scales are clearly "dummy" ones, and are introduced for the purpose of bringing the diagrams into line with the others.

In the case of the $4n$-ordinate method, the diagram for an nth sine harmonic would, similarly, consist of $4n$ equi-spaced vertical scales erected at distances $\pi/4n$, $3\pi/4n$, $5\pi/4n$ . . . &c., respectively from the end of the base-line. The unit of each scale would be made equal in length to $\sqrt{2}$, the successive scales being marked $++--++$ &c., above the base-line, and $--++--$ &c., below.

In like manner the diagram for determining an nth sine coefficient by the $6n$-ordinate method (which may be regarded as an $8n$-ordinate method with the 4th, 8th, 12th, &c., ordinates omitted) would consist of $8n$ equi-spaced vertical scales erected at the respective distances $\pi/4n$, $2\pi/4n$, $3\pi/4n$, &c., from the end of the base-line. The units of the successive scales would be made equal in length to $\pm\sqrt{2}$, ± 1, $\pm\sqrt{2}$, ∞, $\mp\sqrt{2}$, ∓ 1, $\mp\sqrt{2}$, ∞, $\pm\sqrt{2}$, ± 1, &c., where the upper signs relate to the scales above the base-line and the lower signs to those below.

The investigation of the character of the corresponding diagrams for cosine coefficients may safely be left to the reader.

Twice the average ordinate of a periodic curve, as read on one of the above sine diagrams, would give S_n, S'_n or S''_n according to the type of diagram employed. Diagrams of this kind adapted to Fischer-Hinnen's method or its modifications will, on comparison, be seen to be but particular cases of the general "reciprocal-sine" and "reciprocal-cosine" diagrams described in THE ELECTRICIAN article just referred to. The general diagram passes into the particular whenever the number of scales which it contains is made some fixed multiple (such as 4 or 8) of the order of the harmonic for which the diagram is constructed. Thus the diagram for a $2n$-ordinate Fischer-Hinnen method is a $4n$-ordinate reciprocal-sine diagram constructed by dividing the base-line into $4n$ equal parts and erecting scales at the several points of division. If instead of erecting scales at the points of division we erect them midway between the points of division, we get a diagram for the $4n$-ordinate modification of Fischer-Hinnen's method. So, also, a diagram for the $6n$-ordinate modification of Fischer-Hinnen's method is a reciprocal-sine diagram constructed by dividing the base-line into $8n$ equal parts and erecting scales at the points of division.

It must not be forgotten that reciprocal-sine diagrams with a fixed number of scales occasionally assume the special forms indicated above. Thus, in applying a 24-ordinate reciprocal-sine diagram to determine a 3rd harmonic we are actually using an $8n$-ordinate diagram (or what we have elsewhere called a $6n$-ordinate method of the Fischer-Hinnen type), and therefore the 21st, 27th, &c., harmonics are included in the result which is thus inaccurate to that extent. Again, in applying a diagram with the same number of ordinates to evaluate a 6th harmonic, we are, in fact, using a $4n$-ordinate Fischer-Hinnen method, and the result must contain the 18th, 30th, &c., harmonics. In the practical application of fixed ordinate methods the risk of error from this cause can be largely minimised by employing a sufficient number of ordinates.
